Page.
Abosso Gold Mining Co., Ltd., yearly report.... 115
Abrogation of treaty between United States and Russia. Editorial.... 763
Accidents due to falling bodies.... 718
  Human factor in.... David S. Beyer.... 140
Acetylene.... 560
Acid-proof ink.... 422
Adjustable drop-light.... 843
Adulteration of oils, detecting.... 737
Africa, Benguella railway, Portuguese West.... 317
  Deep-level ores of the Rand.... 78
  Diamond developments in South.... C. A. Tupper.... 169
  Dredging on Gold Coast, West.... 707
  Gold Coast mines, West.... 653
  Mining developments, West.... 117
  Tin-gravel mining in West.... 228
  Tin mines, South.... 720
African timber, West.... 109
Age of coal-bearing rocks.... 735
Agitation in Pachuca tanks, principles in.. A. Grothe.... 80
Agitator, historical notes on the air-lift.... J. W. Swaren....409, 495
Agitators, measuring specific gravity in.... Charles F. Spaulding.... 358
Agricultural entries on public land.... 843
Agua Prieta.... 668
Aguascalientes smelter, American Smelting and Refining Co.... 122
Ahmeek Mining Co.... Editorial.... 541
  Six-month production.... 81
Air, composition of.... 268
  Compressors.... Editorial.... 314
  Compressors, buying.... R. L. Webb.... 222
  Hammer drills.... C. A. Hirschberg.... 359
  In cyanide processes, preliminary treatment of water and.... George A. James.... 415
  Lift agitator, historical notes on.... J. W. Swaren....409, 495
  Pipes for rock-drills.... 628
  Receivers to equalize load.... 20
Ajax Mining Co....121, 599
Alabama iron deposits.... 108
Alabama's gold production, 1910.... 378
Alaska and its problems.... Editorial.... 611
  Before Congress.... Editorial.... 641
  Chichagof district.... V. H. Wilhelm.... 264
  Coal-lands decision by Supreme Court.. Editorial.... 732
  Coal-lands question....25, 84
    Ditto.... Editorial.... 1, 66
  Coal mines and a coal monopoly... H. Foster Bain.... 406
  Coal mining commission, petition for.... 179
  Comparisons of fuel costs in the dredging field of.... E. S. Rust.... 593
  Controller Bay controversy.... Editorial.... 190
  Copper district.... 663
  Cunningham coal-land decision.... Editorial....1, 66, 155
  Cyanide plant at the Treadwell mines.. W. P. Lass.... 514
  Difficulties of navigation on coast of.... Editorial.... 435
  Dredging at Dawson.... 296
  Fairbanks 1910 output.... 118
  Gold production.... 721
  Kuskokwim river district.... H. W. Reeth.... 77
  Mine, Nevada county, California.... 303
  Mining laws.... H. W. Reeth.... 173
  Nizina district copper deposits.... 203
  Petroleum.... 749
  Placer mine tax.... 118
  Placer mining in.... E. H. Thomas.... 17
  Portland Canal district.... R. G. McConnell.... 104
  Problem of transportation in.. Duncan M. Stewart.... 620
  Prince William Sound mines.... 263
  Tin-dredging in.... H. G. Peake.... 652
  Valdez.... 330
  Visit of Secretary of Interior.... Editorial.... 374
  Visited by Gifford Pinchot.... 389
  Winter closing in.... Editorial.... 436
Alaska Industrial Co.... 498
Alaska Juneau Gold Mining Co.... 148
Alaska Mexican Gold Mining Co....25, 179, 242, 565, 601, 633
  Ditto.... Company report.... 433
Alaska Treadwell Gold Mining Co.... 179, 242, 273, 396, 534, 601, 786
  Ditto.... Company report.... 509
Alaska United Gold Mining Co....58, 179, 273, 427, 565, 633
  Ditto.... Company report.... 308
Alaskan coalfields, cancellation of claims in.... Editorial.... 343
  Gold camp, revival of.... 235
  Problems.... Editorial.... 404
  Problems, first step in solution of.... Editorial.... 345
  Situation.... Walter L. Fisher.... 674
  Situation again.... Editorial.... 672
Albert, Talbot J.... German Potash Syndicate.... 681
Aldrich, Jr., T. H.... Electrolytic oxygen in cyanide solutions.... 483
Alice Gold & Silver Mining Co.... 88
Allen, A. W.... Duty of grinding-pans.... 420
  Ditto.... Mill and cyanide plant records.... 708
  Ditto.... Titrating cyanide solution in presence of silver.... 51
Allen, Carl A.... Vanadium deposits in the Caballo mountains, New Mexico.... 376
Allen, E. T.... Sulphides of iron and their genesis.... 413
Allen, Irving C... Government specifications for purchase of fuel oil.... 226
Allen American Manganese Steel Co., Edgar.... 835
Allouez Mining Co., six months production.... 81
Alloy for metal patterns.... 718
  Monel metal....20, 172
Alluvial deposits.... 659
Along Mexican trails.... Donald F. Foster.... 688
  Ditto.... Alexander J. Fraser.... 587
Alps, tunnel-driving in.... W. L. Saunders.... 13
Alta Consolidated Mining Co....182, 600

Page.
Aluminum.... Juan Felix Brandes.... 595
  Corrosion of.... 134
  For honing.... 52
  In paint.... 83
  Production in 1910.... 418
  Uses of.... 20
Alunogen.... 497
Amalgamated Asbestos Co.... 662
Amalgamated Copper Co.... Editorial.... 343
Amalgamated Nevada Mines & Power Co.... 176
Amalgamated Pioche Mines & Smelters Corporation..178, 244
Amended location notice.... 843
America, cyanide in.... 79
American Administration on Mexico.... Editorial.... 763
  And Australian copper production.... 176
  Engineers in Bengal.... Editorial.... 103
  Influence on mining operations controlled in Europe.. C. A. Tupper.... 252
  Living conditions.... Editorial.... 126
  Mining law, revision of.... Editorial.... 793
  Permissible explosives.... 657
  Phosphate plants, modern.... James A. Barr.. 623
  Trade.... Editorial.... 435
American Association for the Advancement of Science.. Editorial.... 825
American Institute of Mining Engineers and Mining & Metallurgical Society, suggested consolidation.... Editorial.... 97
  Excursion program.... 419
  Formation of local sections.... 12
    Ditto.... Editorial.... 2
  In Japan.... 775
    Ditto.... Editorial Correspondence....714, 746
  Japan excursion program.... 528
  Los Angeles section.... Editorial.... 642
  Proposed amendment to the Constitution.... 449
  Provisional program.... 448
  Sail for Japan.... Editorial.... 511
  San Francisco meeting....199, 493
    Ditto.... Editorial....314, 374
  Spokane section.... 758
    Ditto.... Editorial.... 732
  Visit to California.... Editorial.... 436
  Visit to Japan.... Editorial.... 764
American Metal Company.... 555
American Metallurgical Society.... 359
American Mining Congress committee on general revision of mineral land laws, report of.... Edmund P. Kirby.... 544
  Election.... Editorial.... 573
  Meeting.... Editorial.... 373
  Meeting at Chicago.... Editorial.... 542
American Peat Society.... Editorial.... 313
American Smelters Securities Co.... 594
  Ditto.... Company report.... 433
American Smelting & Refining Co.... 116, 122, 271, 277, 555, 594, 632, 660
  Ditto.... Company report.... 340
American Society for Testing Materials.... 361
  Specifications for spelter.... 289
American Zinc, Lead & Smelting Co.... 598
Ammonium nitrate explosives.... 143
Amur gold regions.... 285
Anaconda fume commission.... 115
Anaconda Copper Mining Co.... 81, 88, 115, 208, 240, 364, 398, 461, 504, 636
  Ditto.... Company Report.... 433
Analysis, cost.... G. L. Watson.... 710
  Of fire-clays.... 361
  Of zinc-dust.... 356
Ancobra Exploration & Dredging Co., Ltd....707, 782
Aneroid and compass for railroad reconnaissance.... 619
Angel Mining Co.... 149
Angels, California, important development at.... 389
Anglo Deep mine, gas in.... 266
Anglo-French Financial Company of Canada.... 362
Anglo-Westfalian Kent Coal Syndicate.... 841
Annual labor....207, 268
Antimony.... 330
Apex law.... 529
  Right.... Editorial.... 825
Apex Porcupine Mines, Ltd.... 370
Appalachian gold production, southern.... 49
  Metal production in 1910.... 416
Appelbaum, Misha E.... Copper Review....104, 232
Appraisal of copper mines.... J. R. Finlay.... 328
  Of mines.... Editorial.... 280
Appropriations for Bureau of Mines.... Editorial.... 701
Arbitration treaties.... Editorial.... 374
Arbuckle mountain, Oklahoma, drill operations in.... 656
Are veins richer in depth?.... Editorial.... 281
Argentine constructs moles for petroleum resources.... 713
  Oil in.... 324
Argo smelter.... 367
Argonaut Mining Co.... 502
Arivaca Gold Mines Co.... 694
Arkansas and Virginia manganese production, 1910.... 385
Arizona and New Mexico statehood bill.... Editorial.... 220
  Hammer-drills used by Ray Consolidated.... 360
  Metal production....457, 786
  Mine output, 1910....118, 148
  Proposed new mill.... 25
Arizona Commercial Copper Co....56, 427, 502, 723
  And Superior & Boston Copper Co. plan consolidation....362, 366
Arizona Copper Co....26, 116, 241, 532, 785, 813, 814
Armour & Company.... 642
Arms in tunnels, long column.... 687
Art and Industry.... Editorial.... 344
Asbestos....113, 330, 361, 596
  Deposits at Newfoundland.... 330
  Glued to iron.... 628
  In United States, production of.... 594
  Occurrence.... 83
  Uses of.... 298

169998

MINING AND SCIENTIFIC PRESS

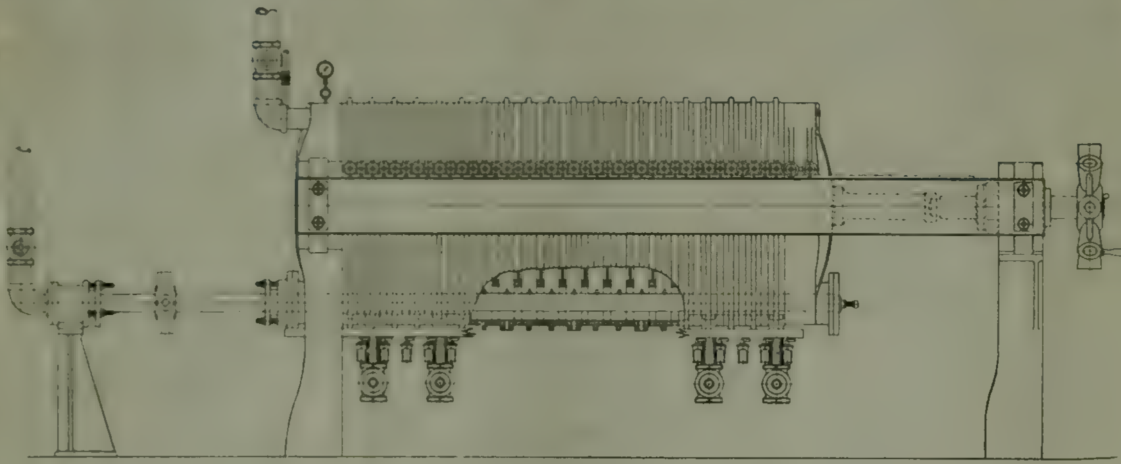
ESTABLISHED 1860

Whole No. 2658 VOLUME 103 NUMBER 1 SAN FRANCISCO, SATURDAY, JULY 1, 1911 THREE DOLLARS PER ANNUM Single Copies, Ten Cents

CALIFORNIA STATE

INDEX TO ADVERTISERS, PAGE 56 PROFESSIONAL DIRECTORY, PAGES 6-24 BUYERS' DIRECTORY, PAGE 54

Merrill Sluicing Clarifying Filter



A COMPACT, ECONOMICAL and EFFICIENT machine for filtering cyanide solutions. The filter cloths within the press are kept free from accumulated slime cake, and a large capacity per unit of filter area is therefore possible.

An absolutely clear solution is obtained, and as filtering operations are conducted at a very low pressure, both power and general operating expenses are reduced to a minimum.

Furnished in units of from 100 to 1000 tons of solution daily capacity.
Prices and specifications furnished on application.

MERRILL METALLURGICAL CO.
ENGINEERS
143 Second St., San Francisco

THE PIONEER MINING MACHINERY HOUSE OF THE WEST.

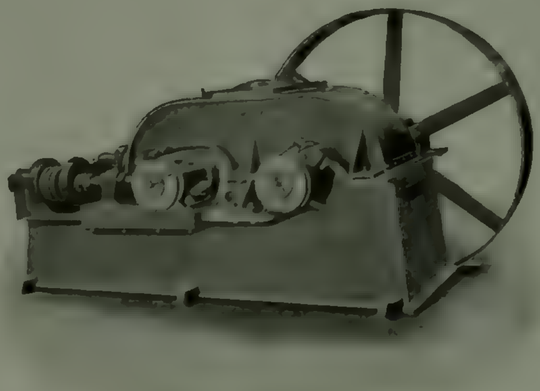
THE HENDRIE & BOLTHOFF MFG & SUPPLY CO.

DENVER, COLO.

STEAM ELECTRICAL AND HYDRAULIC ENGINEERING ~ MINE AND SMELTER SUPPLIES.

Parallel Rolls

Strongest, Simplest, Most Durable and Most Efficient Rolls on the Market.



Self-contained construction. Removable journal boxes, so arranged as to present three bearing surfaces before requiring rebabbitting. Movable roll carried on a sliding saddle, and both shafts always parallel regardless of wear.

ASK ANY MILLMAN WHO HAS RUN THEM—HE KNOWS

The Hendrie & Bolthoff Mfg. & Supply Co.

EDITORIAL

THE American Institute of Electrical Engineers held its annual convention in Chicago last week and the session was most interesting.

EXPORTS of iron and steel for the year just ended show an encouraging increase, the estimate being $235,000,000, as compared with the former record of $184,000,000 in 1908.

IT is estimated that the poultry and egg production of the United States for the current year will have a value of $1,000,000,000. Why hunt for Porcupines when Plymouth Rocks are available!

MANY corporations have offered to compromise the claims for the Federal corporation tax of last year, and the ruling has been made by the Department that no offer of less than $10 in addition to the assessment will be accepted.

THE latest 'Trust' to be dissolved is the E. I. du Pont de Nemours Company, with its affiliated powder-manufacturing companies. The interlocutory decree fixes October 16 as the date for providing a plan of dissolution, so that the supply of powder for military purposes and the work of excavating the Panama Canal may not be interfered with.

AN interesting suggestion has been made by Mr. Horace V. Winchell to the effect that the attention of the President should be called to the desirability of appointing to the Supreme Court, whenever a vacancy shall occur, a judge familiar with mines and mining. It is to be hoped that such an appointment may be made, since many matters relating to mining come before this, our court of last resort.

PANAMA CANAL bonds showed unexpected market strength, the issue of last month selling at an average premium of 2.25, corresponding to an interest yield of 2.95 per cent. When this is compared with the 3.10 per cent of French *rentes*, and the 3.30 per cent of German Imperial threes, it would appear that the difference must be due to the market value of patriotism, for the security of the foreign issues is unchallenged.

FINAL DECISION has been rendered on the Cunningham coal lands in Alaska, the evidence clearly indicating that agreements had been entered into previous to making the entries. So the illegal segregation of public lands has been prevented. But this is merely a negative accomplishment: what is most needed is wise and energetic constructive legislation that will allow coal lands in Alaska to be developed promptly. The friends of Alaska have at times acted unwisely and frequently speak rashly, but their cause is just and a speedy remedy should be devised. Walter L. Fisher, Secretary of the Interior, has shown commendable insight in dealing with the situation so far, and an early solution of the Alaska coal problem will be anxiously awaited.

EUROPEAN methods of tunnel-driving, discussed by Mr. W. L. Saunders in a paper abstracted in this issue, have produced results superior to those in America. This is true despite the fact that in part the same machinery is used in both countries, and on some American work a number of experienced European workmen have been employed. Mr. Saunders attributes the result mainly to the greater discipline of the men, largely a result of the length of time that a particular crew work together in order to complete one of the great Alpine tunnels. Sending machines from the north to the south portal of the Loetschberg tunnel failed to affect the relative rate of progress. Bringing to the Cowenhoven at Aspen experienced foremen from the Arlberg, notably expedited matters. The man behind the drill is important, as is the drill. Any experienced engineer recognizes the importance of discipline in obtaining speed. How important this is was shown in the tunnel work on the Los Angeles aqueduct when, contrary to expectations, the cost per foot did not increase with progress into the mountain. The proficiency acquired by the men more than offset the increase in cost due to longer transportation of material. Careful training of men, keeping them interested and satisfied, so as to keep the same men at the same job, is the secret of success. Aside from that, however, the drill-carriage used at Loetschberg is worth imitating. Certainly remarkably speedy 'set-ups' were made possible by using it, and that in turn made it feasible to use short holes rather than the long ones standard in American practice. How far these methods may be adapted to advantage in America is not to be predicted offhand, but on any long tunnel when conditions approach those in the Alps, they should be given serious consideration, in spite of different labor conditions.

Local Sections of the American Institute of Mining Engineers

Officers of the American Institute of Mining Engineers recently have taken steps to secure the organization of sections wherever the membership and local interest seem to justify. This we believe to be an important move in the right direction. It is a waste of opportunity that the four thousand or more members of the Institute should have no means of increasing their mutual acquaintance other than semi-annual, none too well attended meetings, and no effective bond of union other than that of receiving the same technical literature. In San Francisco and its environs, there are about 120, and in California 300, members. These members had an opportunity, through the Institute, to meet in 1899, and will have another in 1911. The sessions held in the intervening years have necessarily been at a distance too great to afford any real or effective opportunity for California members to attend. The same situation, to only a little less striking degree, exists for members in Colorado, Montana, the Lake Superior district, and everywhere, in fact, except in and adjacent to New York City. Even there, there has not been that opportunity for frequent meeting, and for development of a real bond of union among members, that there must be if the Institute is to serve its highest purpose. A strong, healthy development of right ideals among mining men, can only flow from personal acquaintance and growth of mutual respect. The written or printed word, while reaching more people in less time, does not supplant entirely the influence of speech and personal contact. All of us, probably, have had the experience of misjudging a man known to us only from second-hand information. When we came to meet him, he proved to be quite a decent fellow after all, and ultimately we acquired a real confidence in his intentions and ability. It takes but a moment's consideration to perceive how greatly the effectiveness of an engineer is increased by the broadening of his acquaintance. To promote this is, in our opinion, one of the proper functions of a professional society.

It will be remembered that the disinclination of the officers of the Institute to organize local sections was one of the impelling causes of the formation of the Mining and Metallurgical Society, and no one who has attended a meeting of any of the sections of that society has failed to see the advantages of that form of organization. The Institute has a much larger list of members, and it includes, necessarily, a considerable number whose interest in mining is only secondary, but at the same time it does include practically all the active men in the profession, and in a large number of communities it affords splendid material for a local society. We present this week the rules under which sections may be formed. They are modeled after those of the American Institute of Electrical Engineers, which has been conspicuously successful in its solution of the problem of local sections. These rules provide for safeguarding the interests of the Institute in every proper manner and at the same time allow all proper latitude to the local organization. According to the constitution of the Institute, the latter can not "officially approve or disapprove any technical or scientific opinion or any proposed enterprise." This does not inhibit a local section, if it choose, from throwing its influence for or against legislation or other projects that may seem to it of sufficient concern. If the Section acts unwisely, or in such manner as to at any time compromise the Institute as a whole, the Council can at will withdraw its financial support and cancel the Section. This is as it should be. There has been entirely too much fear of taking a stand on public matters directly concerning mining and mining engineers, and it is desirable that in any instance the matter should be threshed out by those most intimately concerned. They, having a better acquaintance with the situation, are best qualified to act. The rule prohibiting the Institute itself from taking a stand is altogether wise, so long as the little interest in general meetings makes it necessary to provide that nine members shall constitute a quorum. A more lively concern with the work of the Institute is extremely desirable, and the Council has acted wisely in proposing to build it up on the broad basis of active interest, locally, among members.

Muntz Metal Plates

The valuable description of milling practice at the Komata Reefs mill which Mr. S. D. McMiken presents in this issue derives added interest from so closely following the description by Mr. C. A. Chase of the work at the Liberty Bell. Comparisons are always useful, and the divergent results obtained by the use of muntz metal plates at the two mills is an interesting minor matter. It may be urged that in the one mill crushing is carried on in cyanide solution, while water is used at the other; but there is no known reason why cyanide should have any such effect. Muntz metal is an intermetallic compound of copper and zinc. Both mercury and gold are soluble in copper, but neither is soluble in the copper-zinc compound; therefore, as Mr. McMiken observes, absorption of amalgam by the plates is very slight. Possibly the hardness of the plates, found objectionable at the Liberty Bell, is due to the fact that muntz metal can not hold so thick a film as a copper plate, an objection that is accentuated by the lack of absorption of gold into the plate. By far the best plate is one which is made of silvered copper, not scraped too closely during the clean-up. Muntz metal plates were first used in the Hauraki district because copper plates were not to be obtained locally, while muntz metal plates, intended for ship's sheathing, could be had in abundance. Though used successfully in New Zealand, they have found but little favor elsewhere. The cyanide process was first successfully applied at the nearby Crown Mines at Karangahake, and Mr. McMiken's description of the methods of work at the natal place of the Pachuca tank is full of interest.

Utah Copper and Its Critics

The conspicuous success of the Utah Copper Company in the development and exploitation of porphyry copper ore, makes the annual report of its affairs of more than ordinary interest. The magnitude and complexity of the financial as well as technical operations of the company have further attracted attention. One result has been an amount of criticism which, to our recollection, exceeds that heaped upon any other American mining company, and is only rivaled by the activities of the muckrakers in discussing Standard Oil or the 'Anthracite Trust'. As a result, it is difficult to get a fair estimate of the work now being done by the company and its officers. We present this week a rather long abstract from the annual report recently made public, and we regret that limitations of space prevent giving more detail. A perusal of this abstract, or better still a careful study of the original report, will, we believe, convince any competent and unbiased person that the affairs of the company are being well conducted, and that its officers have made an honest effort to present to stockholders and public the facts necessary for a correct appraisal of the property. If fault be found with the report it must be admitted that, as compared with the majority of those issued by American mining companies, it is conspicuously full and fair. It should be remembered that professional opinion as to what is desirable in a company report has been changing rapidly in recent years, and higher standards have been set. In the case of the present company, both its friends and its critics will agree that this is the fullest and most satisfactory report yet made public. In the face of the detail presented, only one with a bysmalithic prejudice will seem to discover a secret mass of corruption and persistent effort to deceive. Our fiery contemporary at Salt Lake City, is not, of course, satisfied; that is hardly to be expected, since with much energy, ability, and in general with good intentions, *Mines and Methods* has shown such prejudice toward the Utah Copper Company as to prevent its criticism being taken seriously. In commenting on the present report it has been attempted to show that approximately a half million tons has been milled but not accounted for. To our way of thinking, the laboriously discovered discrepancies in figures are the natural result of the fact that freight is paid on ore as mined, and mill recovery is figured on dry weights. Again, an elaborate argument is built up to prove that the company lost heavily by continuing underground mining, and then the use of steam-shovels is condemned. If this means anything, it logically follows that the company would have made the most money if it had not mined at all—a strange conclusion in view of the figures presented by the public accountants who had full access to the books of the company. Evidently our contemporary suffers a handicap in lacking data to prove its thesis; and just possibly the data do not exist. If *Mines and Methods* desires to do good work by drawing on esoteric information, we recommend an article or two on the re-location of phosphate claims by those who would maintain that a bed of oölite is a vein. For this friendly suggestion we expect to be roundly condemned, but, if so, we shall be members of a large and growing 'Ananias Club' that at least includes some interesting and respectable members.

Our New York contemporary, *The Engineering and Mining Journal*, which has acquired a part of the staff of *Mines and Methods*, if not of its prejudices, also criticizes the report. In part we agree. The company does not make any allowance for depreciation, despite the repeated recommendation of its accountants. Disregarding arguments that may be urged to the contrary, we believe it should do so. Here again, however, standards have been rapidly changing, and the management is not absolutely unreasonable in its contention that this provision can safely be made later. This does not rob the criticism of point, but this practice is too common a one to warrant any over-long sermon. The other criticism is directed toward the large increase in ore reserve reported as a result of additional development and recalculated within the year. As to this we have no information not available to others. We have never seen the drill records or the assay maps of the Utah Copper Company. We have, however, seen and studied those of the Chino Copper Company, which, as is well known, is under the same management and has a corps of engineers that has been largely recruited from the staff of the Utah Copper Company. Our impressions of the methods in use at Chino in calculating reserves are entirely favorable, and it is difficult to believe that the same men would adopt on another similar property methods open to serious criticism. As shown by Mr. Jackling's report, fairly complete data were available for making his estimates. The amount of driving and drilling done within the year, measured by the standards at any other mine, would be enormous, and when two formerly separate properties are consolidated it is usually possible with relatively little development to prove a large amount of intervening ground, because of the collating of information previously available only to the separate corps. The main element, however, is probably the lower percentage of copper required in ore as the scale of operations increases. Lowering a fraction of a per cent the grade that may be profitably worked, nearly always results in increasing the tonnage beyond all apparent proportion to the decrease in grade. This affords an easy explanation of the fact puzzling our contemporary, that the cross-section published in 1910 "should show so much greater depth of ore in certain drill-holes than the same holes showed in substantially the same section in 1909." This of course would not be true in estimating coal properties, with which *The Engineering and Mining Journal* is more familiar. To be specific, however, Mr. Jackling's report shows that the Utah Copper Company is now milling at a profit rock containing a percentage of copper below that which, when negotiations for consolidation of the Utah Copper Company and the Boston Consolidated were first undertaken, the consulting engineer would permit to be even discussed as probable ore. Conditions have changed materially in the last two years, and it is not surprising that some have difficulty in keeping up.

As every public speaker in California says of the Southern Pacific when he rises before an audience, 'We hold no brief' for the Utah Copper Company. We have frequently criticized it in the past, and will in the future when we see just cause; but we protest against an attitude on the part of technical journals that leads them into 'seeing things at night' whenever the name of a particular company is mentioned. The management of the Utah Copper Company has made mistakes. What engineer has not in rapidly building up a great enterprise? But large results have also been achieved, and Mr. D. C. Jackling, Mr. Robert C. Gemmel, and their associates, have pointed the way toward the utilization of enormous masses of rock formerly valueless. They are men having records of honorable achievement as engineers, and it is unwarranted to assume that possible stock-market manipulations of their business associates have led them into falsifying a plain statement of technical performance, and the criticism directed at the report means that, if it means anything.

Milling Practice at the Komata Reefs Mine

By S. D. McMiken

The Komata Reefs mine is situated on the Hauraki peninsula of the North island, New Zealand, shown on the accompanying map. When this mine was first worked, dry crushing with stamps, followed by cyanide treatment, was considered the correct method of treating the gold and silver ores of this field. Accordingly, a dry-crushing plant was built, but it was soon found that this method was not suited to the ore and was far too expensive to warrant its continuance. A change to wet crushing, with subsequent treatment of the pulp by cyanide, proved to be advantageous, and all the subsequent improvements in the milling and treatment of ore have been along the line of wet crushing. The extraction during the dry-crushing period was not high compared with the results obtained with the present method of treatment, although the ore milled during the dry-crushing period was worth more than the ore milled during the period covered by the present practice, the ore at that time being 'selected,' to cover the extra expense involved by the dry-crushing process.

SCREEN TESTS OF ORE

Percentage on	40 mesh.	60 mesh.	90 mesh.	200 mesh.	Through 200 mesh.

Ore after mills....	nil	1.0	22.0	25.9	51.1
Sand in vats......	nil	1.3	23.6	35.0	40.1

EXTRACTION

	Value of tailing.		Percentage.		
	s.	d.	Gold.	Silver.	Value.
Amalgamation on plates..			42.0	5.6	38.0
Sand, by cyanidation....	2	2	94.2	85.6	93.0
Slime, by cyanidation....	0	8	96.5	91.9	95.6
Total, by amalgamation and cyanidation.......	1	5	97.1	89.2	96.4

The following definitions are given, for the sake of clearness: 'Slime' is that product, clayey in nature, but with some fine sand, all of which will pass a 200-mesh screen. 'Fine sand' will pass 100 mesh, but remain on 200 mesh. 'Medium sand' is finer than 60 mesh, remaining on 100 mesh. 'Fine' is all pulp, both sand and slime, ground fine enough for cyanide treatment. 'Middle' is sand which has passed through the tube-mills, but is not yet ground fine enough for cyanide treatment. 'Coarse' is the pulp as it issues from the stamp screens, crushed through a woven-wire screen, 4.5 meshes per linear inch. 'Sand residue' is the sand treated by percolation and sluiced into creek, containing a small amount of unrecovered dissolved metal. Cyanide strengths are in terms of potassium cyanide, although sodium cyanide, 130% KCN, is used in the plant. The short ton of 2000 lb. is used throughout. The assay value is based on gold at 84s. 9d. per ounce, and silver at 2 shillings.

Nearly all the ore now mined is unoxidized, being obtained from between the 400 and 700-ft. levels. The gold and silver occurs in a quartz gangue, mixed with calcite; in places associated with sulphides of iron and copper, and carrying a proportion of about 5 of silver to 1 of gold. In places, manganese silicate occurs, and native quicksilver has been found. The proportion of sulphides, however, is not great enough to warrant the use of concentration in the mill, and the process is accordingly simplified. The ore does not readily decompose; after six months exposure to the air, it shows only a faint acid reaction, and is in every way amenable to treatment by the cyanide process. The country rock, a highly silicified andesite, is much mixed with the vein material, and as a large quantity of this hard rock has to be crushed along with the softer ore, the duty per stamp is lessened considerably.

The ore from the mine is tipped over a grizzly placed on the main mine hopper. This grizzly is made of feather-edged steel bars, and is 15 ft. long by 3½ wide, the bars being placed 1½ in. apart. The main hopper is divided into two compartments, one for the material that passes through the grizzly, and the other for the coarse lumps of ore. The portion that passes through the bars is about 40% of the total. The two sizes are then trammed to the mill, a distance of three-fourths of a mile, in 4-ton cars. The coarse size is tipped into a hopper situated above the crushers and the small size is tipped directly into the main storage hopper of the battery, where it mixes with the material from the rock-breakers, of which there are two of the Blake type, 12 by 8 in., placed directly above the main storage hopper and crushing to 1½-in. ring.

One man looks after both machines, keeping them fed with ore, as well as attending to the friction hoist used for handling the four-ton cars up a small incline to the top of the mill. The ore is then fed by automatic feeders to four batteries of five stamps each, crushing in water through a steel woven-wire screen of 4½ holes to the linear inch. From the batteries, the coarse pulp flows to two tube-mills, thence to an elevator-wheel which raises the pulp to a separating-box where the fine overflows and passes to the amalgamating plates, and the middle is returned to the tube-mills for further grinding. From the plates, the fine passes to another elevator-wheel which raises the pulp to the spitzkasten, where the sand is separated from the slime. The sand is run into the percolation vats, which are furnished with radial distributors of special design, and after treatment by cyanide solution, is discharged into a creek near the plant, the gold-bearing solution being led to precipitation-boxes filled with zinc shavings, and then into the usual storage sumps. The slime from the spitzkasten is run into a settling vat provided with a continuous discharge at the bottom, limewater being added, and is there thickened to about 40% water, and then pumped into Brown & McMiken tanks (Pachuca), where cyanide solution is added, and agitation maintained until the gold and silver has practically all gone into solution. The slime is then pumped into another settling-vat, similar in design to the one already mentioned, and here another thickening takes place, reducing the percentage of moisture to about 45. The solution which is decanted off the settler is run into a vat provided with a sand filter-bottom, and thence to the precipitation boxes. The thickened slime is then pumped from the discharge of the settler to a Moore filter of special design, where the slime is formed into cakes and washed thoroughly, the residue being finally sluiced into the creek. The precipitate from the zinc-boxes is removed during the monthly clean-up, and is treated with sulphuric acid, washed, dried, and fluxed with borax glass in plumbago crucibles, heated in gasoline furnaces of patent design. The resulting bullion is shipped to London and sold at market rates. The amalgam from the plates is retorted, melted, and sold to the local bank in preference to shipping it.

ELEVATION OF B. & M. TANKS.

B. & M. TANKS AT KOMATA REEFS.

The crushing machinery consists of 20 stamps arranged in four batteries of five stamps each, ten stamps to each cam-shaft. The batteries are set on Kauri wood blocks of ample size, which rest on a concrete foundation, giving a firm and satisfactory crushing base. The frame is of the front-knee pattern, strongly braced, and giving little vibration. Each mortar-box weighs three tons and is of the single-discharge type, fitted with back and end liners of hard cast iron. The boxes are bolted down to the wooden blocks with eight 2-in. bolts, a single sheet of rubber packing ¼ in. thick being placed between the wood and the mortar. The weight of a stamp complete with new shoe is, stem 480 lb., head 320, tappet 130, shoe 170, total 1100 lb. The average working weight is about 1030 lb. A system of using the shoes and dies, when half worn out, has been in vogue for over eight years and has effected a great saving. No dies are ever bought, the half-worn shoe being turned upside down and the neck placed in a special casting in the bottom of the mortar-box. This allows the shoe to be worn down to within ½ in. of the neck, when it is pried out and another shoe inserted. Solid cast-iron guides are used, and have given no trouble for years. They are preferable to wooden, or babbitted guides. The tappets are of the 3-key type and seldom slip. Finger props are used to hang up the stamps when required. The usual drop is 6½ in., and the speed is 100 drops per minute, the ore being fed into the mortar by means of an improved Challenge feeder of the rotary table type, a special pawl motion being used in preference to the ordinary 'frying-pan' variety. Both cam-shafts are 6 in. diam. and each carry ten cams of the Blanton type. These cams are preferable to the old double-keyed kind, which give much trouble when they get loose on the shaft. The cam-pulley is also fitted with the Blanton wedge-piece, and never gets loose. Various kinds of screens have been tried, including punched and slotted screens; after exhaustive tests, the steel woven-wire screen has been found to give the best results as regards efficiency and cost. The kind now used is made to order in America, and is very good, a set of screens having lasted nine weeks. The ore is crushed through a woven-wire screen of 4½ holes to the linear inch, the thickness of the wire being 20-gauge. The discharge is kept about 4 in. above the dies, and about ten tons of water per ton of ore is used in crushing. The duty per stamp is five tons per day of 24 hours, and the horse-power used 48, including friction. Exhaustive trials of various makes of shoes, steel and iron, have been made, and the best, from a commercial point of view, is a shoe made of a special mixture of hard white iron manufactured by a local foundry. The consumption of iron, in shoes, per ton of ore crushed is 0.67 lb. The coarse pulp from the stamps is delivered into a steel launder running the full length of batteries, and immediately in front of the mortar-boxes. This launder is set with a grade of 1 in 12 in order to conduct the coarse product of the stamps to the tube-mills, at a lower level. This launder is divided into two sections just before reaching the tube-mills, so that each mill gets an equal quantity of pulp to grind (see grade of pulp in tables). The power used by the battery is furnished by a 6-ft. Pelton wheel, working under a head of 170 ft., and two single-cylinder condensing engines, supplied by two locomotive-type boilers, coal-fired. In winter, the water-power amounts to about 80 hp., but in summer the whole battery is run by steam. It requires about 140 hp. to run the whole plant.

Grinding is accomplished in two tube-mills, one of which is 16 ft. long by 4 ft. diam., and the other is 15 ft. long by 4 ft. 4 in. diam. The former was the first steel-shell tube-mill made in New Zealand for grinding battery pulp. It is furnished with spur gearing and runs on trunnions. The second mill was made out of a 'White' rotary dryer, cast-iron shell, running on trunnions. At first, this mill was run on friction rollers, but as these proved unsatisfactory, end trunnions were substituted, and there has been no trouble since. Both of these mills are lined with Brown's patent liner, which consists of a liner of hard cast iron, with ribs bolted over it; they last 22 months, grinding 28,500 tons of hard quartz, during the life of a set. The consumption of iron is 0.48 lb. per ton of ore ground to a finished product, 50% of which will pass a 200-mesh screen. This lining has been adopted by most of the mining companies in this field, in preference to all others, and will probably supersede all others in countries where fine-grinding in tube-mills is in vogue.

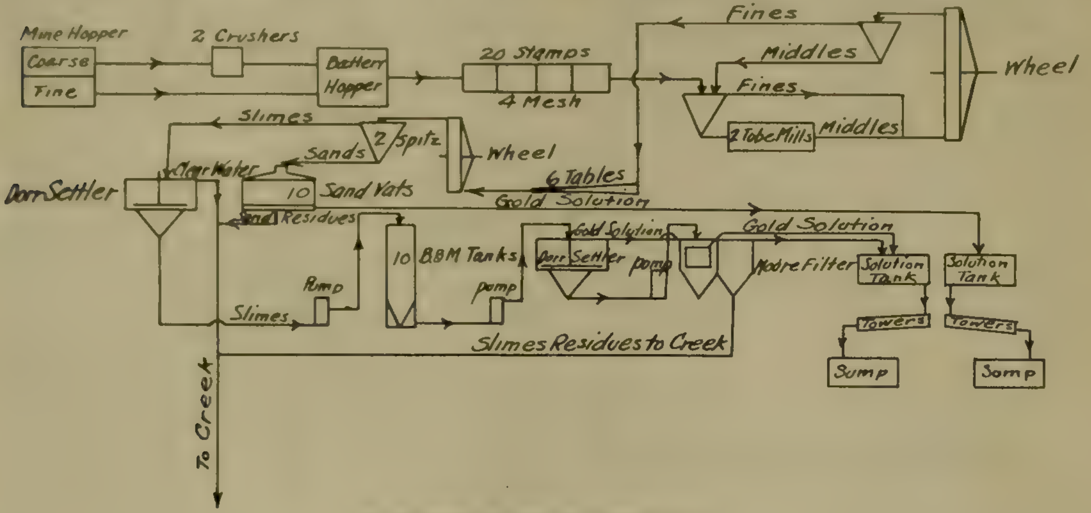
Each mill is fed from a pointed box, 3 ft. deep and 3 ft. square at top, by means of a pipe $1\frac{1}{2}$ in. diam. projecting into the trunnion of the mill. The size of this box is so adjusted that a large proportion of the water together with some slime is allowed to run off the top into a launder, so that the product issuing from the pipe is about $1\frac{1}{4}$ parts water to 1 part ore, by weight. It has been found that this proportion is the best for grinding our ore in tube-mills. The 16 by 4-ft. mill revolves at 29 revolutions per minute, and the 15 by 4 ft. 4 in. at 28 revolutions, according to the formula $R = \frac{200}{\sqrt{D}}$, where R equals revolutions per minute and D equals interior diameter of mill in inches. This speed has been found to give the best results, and the formula is recommended to users of tube-mills. The flints used are French flints about the size of a hen's egg. Larger and smaller flints have been tried, but this size gives the best results. Selected pieces of hard quartz were also tried but proved unsuitable. The charge used in the mills is such that the level of the pebbles is just even with the lower edge of the discharge orifice, which in this case is 8 in. diam. and is furnished with a screen of three holes per linear inch, in order to prevent the flints from escaping with the ground material. The wear of flints per ton crushed through stamps is 2.2 lb. Each mill takes 25 hp. when running at the above speed, and there are practically no repairs, other than renewing the lining and replenishing the supply of flints. Each mill is furnished with a Heywood & Bridge friction clutch, which is much better than fast-and-loose pulleys. At this battery, these two mills have been running for years, and the trunnion bearings are as good as when first put in, the original babbitt metal being still there. The whole of the floor under the tube-mills is finished in concrete, and a gutter leads into a small sump in order that any spilt sand may be picked up. From the discharge end of the tube-mills a steel-lined wooden launder conveys the middle, fine, and overflow from the tube-mill feed-boxes to an elevator-wheel, 18 ft. diam., which lifts the pulp to a pointed box furnished with a 3-in. discharge cock at the bottom, and an upward current of water. This box serves to separate the material that is ground fine enough for treatment, from the coarser product, which issues from the 3-in. discharge and is returned to the tube-mills for further grinding. The product which is too coarse for treatment is thus returned again and again to the mills until ground fine enough for treatment by the cyanide process. The elevator-wheel is built of wood and iron, the spokes and rim of wood, and the hub and buckets of iron. This wheel works well and has given no trouble since it was built, five years ago. (See grade of pulp after mills.)

From the overflow of the separating-box, the fine pulp flows in a wide launder to the amalgamating room. During its passage along this launder the pulp is automatically sampled in duplicate, and these samples taken daily for assay. The amalgamating room is situated some distance from the stamps and is built upon the solid ground, hence there is an entire absence of vibration. The floor is cemented throughout, and is given a fall to one side, 1 ft. in 15 ft. This allows all spilt material to run into the main pulp launder from the tables, the launder being situated underneath the edge of the floor. There are six amalgamating plates of muntz metal, 10 by 5 ft.; copper plates were tried years ago, but were afterward replaced by plates of muntz metal, which are more easily kept in order and save a higher percentage. There is practically no absorption of gold, and consequently very little value is locked up in the plates. A little dilute sulphuric acid is rubbed on the plates now and again; outside of this nothing is done to them beyond adding mercury as required. A device for turning the flow of pulp off the plates, one at a time, when cleaning up, is used, and the diverted pulp is returned to the elevator-wheel. There are two riffles at the bottom of each plate, as well as a mercury trap to each, and finally there is a large mercury trap in the main launder carrying the pulp away from the plates to the second elevator-wheel. The recovery by amalgamation is 38% of the total value. The plate room is under lock and key, and is only entered by the amalgamator when necessary.

The pulp from the tables is lifted by a wheel, similar to the one described, to a height of 16 ft., and delivered into a steel spitzkasten, furnished with an upward current of water, and a 2-in. discharge cock at the bottom. The spitzkasten is 4 ft. square and the sides slope at on angle of 60°; the overflow passes to a second one, 6 ft. square with similar sloping sides, also provided with a 2-in. discharge and upward current of water. This water supply is kept at a constant head of 40 ft. above the 'spitz.' This arrangement has been found to give the best results for separating the sand from the slime. The product issuing from the bottom of each 'spitz' is allowed to mix in a common launder and flow to the sand-treatment plant, while the overflow from the second 'spitz' goes to the slime-treatment plant.

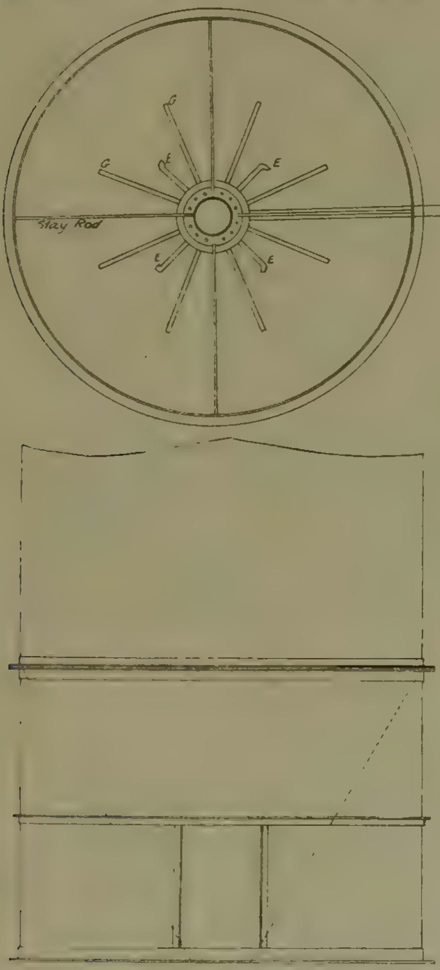
All the separated sand is conveyed to the sand vats, nine in number. These are built of steel, and are 22 ft. diam. by 8 ft. deep. Each of these vats is fitted with a filter-bottom, consisting of half-round slats of wood, 1 in. wide and 1 in. apart, supported on 4 by 1-in. wooden laths on their edge, and over the slats is stretched a filter-cloth of ordinary jute sacking. This cloth is firmly fixed all round the edge of the vat by means of $\frac{1}{2}$-in. diam. rope, caulked into a groove. These cloths last about three years, are very cheap, and easily put in place. Each vat is furnished with a distributor consisting of a wooden launder divided into four divisions, discharging at different peripheral points, the feed being at the centre, and the whole apparatus revolving on a central spindle by the force of the sand and water leaving the curved ends of the divisions. This distributor fills the vat evenly, little shoveling being required to level the top of the charge, previous to treatment by cyanide. The surplus water is taken away from the centre of the vat, and conveyed to a pointed box, 12 ft. square and 12 ft. deep, where lime-water is added, and the fine sand which has escaped from the vat is settled and pumped back to the launder which conveys the slime to the slime-treatment plant. The usual charge for a vat is 80 tons of sand, the grade of which is given in tables. The sand is allowed to drain as dry as possible, assisted by a small vacuum pump, if necessary, and is then sampled by boring holes with a special sampling auger, the holes being bored to a depth of 6 ft. This sample is taken in duplicate, and assayed in duplicate, and the result recorded. The amount of moisture left in the sand before treatment by cyanide is usually about 14 to 15 per cent.

A wash of 20 tons of cyanide solution of 0.05% KCN is then run on the top of the charge, and percolation started. This wash serves to pave the way for the strong solution, and it is percolated rapidly through the charge, passed through a zinc precipitating box, and into a weak sump, where the solution is sampled, and if the assays show no value, the solution is thrown away, as it is too weak to be of any further use. The first wash dissolves very little of the gold and silver, but is useful in reducing the consumption of cyanide when the strong solution is put on. The first wash is allowed to drain off, and then 20 tons of solution at 0.8% is run on the charge and percolation continued. As soon as the whole charge is saturated with the strong solution, and there is still about four inches of solution on top of the charge, percolation to the precipitation-boxes is stopped, and the solution is pumped back to the top of the charge by means of an adaption of the well known air-lift, one to each vat. The strong solution is thus kept circulating for eight days without leaving the vat, and is thoroughly aerated at the same time. Caustic soda is added to the strong solution, in order to provide sufficient protective alkalinity (Clennell's method of estimation being used), and a considerable saving in cyanide is effected by its use. The strong solution is then allowed to percolate from the vat into the strong-solution zinc-boxes, and thence into the strong-solution storage-sump. When the strong solution leaves the top of the charge dry, weak solution of 0.08% is pumped on, and about 200 tons of this weak wash is passed through the charge, the weak solution being passed to the weak-solution zinc-boxes, of which there are two, and thence into the weak-solution storage-sump. Finally, a water-wash of about 10 tons is put on the charge, and percolated through a separate wash-solution zinc-box, into a last wash-sump. The time taken by the washes is generally about 14 days, and after all the final wash has drained off, a door in the bottom of the vat is opened and the whole charge of sand is sluiced out, by water under a pressure of 65 lb. per square inch, into the creek. The cloth is swept clean with a coarse broom, the door put on again, and the vat filled with water ready for a fresh charge. It has been found beneficial to fill the vat with water, so that the overflow takes place as soon as filling starts. This prevents an undue settlement of fine material on the cloth, which, if allowed, would hinder the rate of percolation.



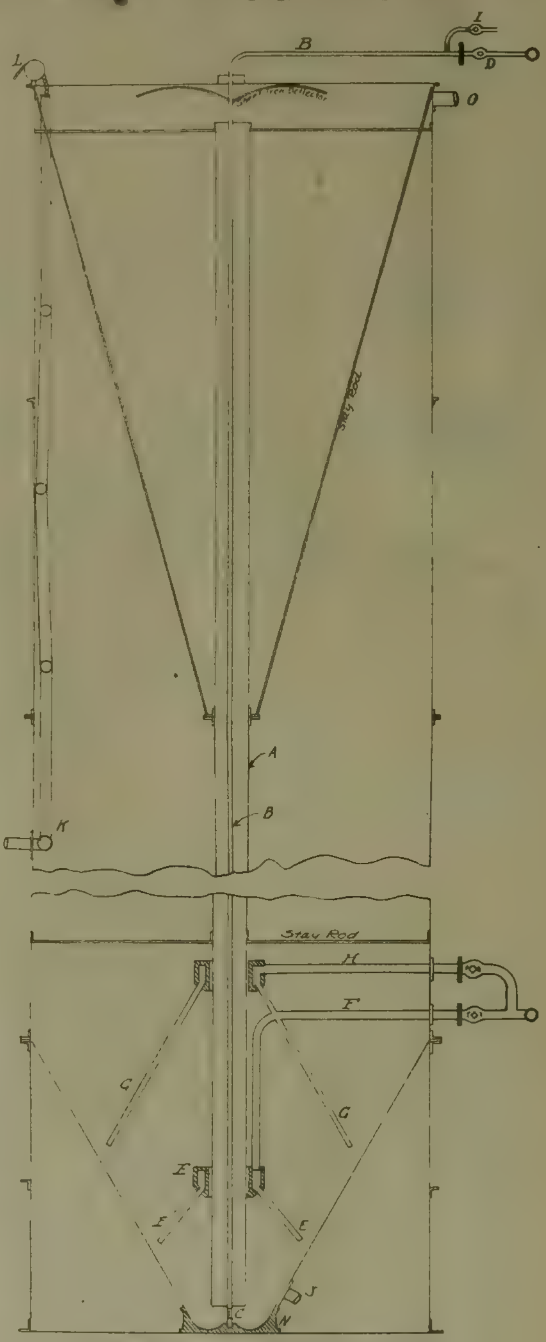
FLOW-SHEET OF KOMATA REEFS MILL.

The slime and fine sand passing 200 mesh, from the overflow of the second spitzkasten, is conveyed by launder to a mechanically operated settler provided with overflow launder at top. This settler consists of a steel vat 22 ft. diam. by 8 ft. deep, with conical bottom. Lime-water is added to the slime as it passes along the launder to this settler, and the slime settles very rapidly, the overflow being quite clear. The lime is fed automatically into a mixer at the average rate of 20 lb. per ton of dry slime, but there is a controlling device whereby from 1 to 50 lb. per ton can be fed as required. The thickened slime flows from the bottom discharge of the settler continuously, and contains an average moisture content of 40% water. This thick slime is piped a short distance to a double-plunger outside-packed pump, each plunger of which is 6 in. diam. by 15-in. stroke, geared, with cast iron mushroom valves. The wear and tear on valves and plunger is not great, the plungers being renewed every eight or nine months, and the valves every four or five months. By means of this pump the slime is elevated through a 3-in. pipe to the Brown & McMiken patent air-agitation tanks (Pachuca), of which there are ten, each 38 ft. high by 10 ft. diam., built of steel, with a cone of 55° pitch, and furnished with the usual air-lift and pipes. These agitators were first used at this (Komata Reefs) mill, but their use has extended all over the metallurgical world, as they are the most economical and efficient agitators yet invented. The cost of upkeep of these agitators is very low, as they only require a new 'nozzle' valve on the pipes now and then, and only 8 hp. is required for the whole ten, using compressed air at 22 lb. per square inch. No trouble is experienced in keeping the charge agitated while filling or emptying the tanks, and there is no accumulation of heavy material on the conical bottom. The slime is diluted by adding cyanide solution in such quantity that the total solution and moisture represents 65% of the whole. Each tank holds 40 tons of dry slime. The cyanide solution is put on at 0.1% strength, and agitation is kept up for seven or eight days, when all the metals are in solution. The slime is then pumped by another plunger pump to a second settler. Here the slime is thickened to 45% moisture, the cyanide solution continuously decanting into a sand filter. This sand filter is a steel vat, 22 ft. diam. by 4 ft. deep, furnished with a lath bottom supporting hessian cloth, which is covered with a layer of battery sand, about 4 in. deep. The solution percolates through this layer of sand, which clarifies it, and passes to the slime-solution zinc-boxes, of which there are two, and thence into the slime-solution sump. The thickened slime from the second settler is then pumped by means of a plunger-pump into the slime-tank of a modified type of Moore filter. This type, termed the turnover filter, was first used in this mill, being designed by me in 1906. It has proved to be economical in working cost as well as being cheap to install. The filter consists of ten cells, each 7 ft. square, formed by placing sheets of V-shaped corrugated iron inside a frame of 6 by 3-in. timbers, grooved on the inside to receive the edges and ends of the corrugated iron, the whole being covered with 8-oz. duck, fastened to the frame by means of slats nailed over the duck. A corner of each frame is bolted to a Y-shaped arm of cast iron, which is keyed to a shaft which forms the pivot on which the filter turns over.



BROWN & McMIKEN TANK (PACHUCA).

The inside of each cell is connected to a 2-in. header pipe by means of a flexible piece of suction hose and union joint, the 2 in. header pipe being in turn connected, by a piece of suction hose, to the pipe leading to the vacuum pump. The filter contains an area of 800 sq. ft. of filtering-surface, and is capable of treating efficiently 50 tons per day of 24 hours. The filter is lifted by a worm-geared hoist which allows the filter to be suspended in any position required, the discharging platform being lifted by a second drum on the same hoist. The washed slime-cakes are dropped into a mixer, where water is added and the whole mixed up into a slime again and run into the creek. In practice, a cake 1¼ in. thick is built up in about 30 min., under a vacuum of 24 to 26 in., produced by a Tangye belt-driven pump, 6 in. diam. by 12-in. stroke, which delivers the solution into another sand filter, similar to the one already described, and thence into the zinc-boxes. When the filter cells are immersed in the wash-tank, the solution is pumped direct to the wash-solution zinc-boxes, and flows back again to the wash-tank, thus maintaining an even quantity of solution in the wash-tank. This wash solution is generally about 0.03% strength. The cakes are dried as much as possible before being discharged, and they retain 25% moisture. The cycle of operations, namely, forming cake, washing, and discharging, takes 1¼ hours.

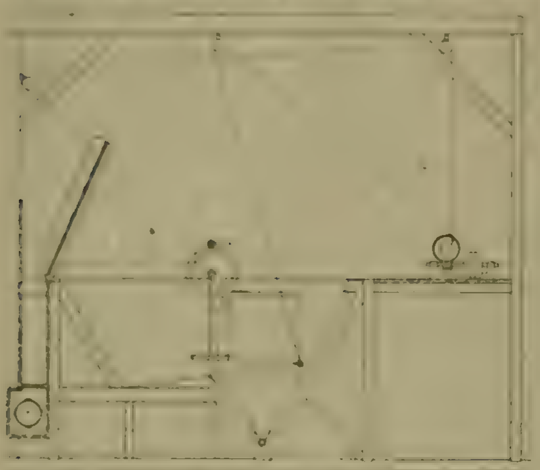


BROWN & McMIKEN TANK (PACHUCA).

The precipitation room is 42 ft. long by 22 ft. wide, and the windows are all securely barred; one wall is fitted with openings, so that the interior of the room is always under observation. The floor is concrete, finished with neat cement, and provided with gutters to convey any spilt material to a small sump. In one corner, a reinforced concrete strong-room contains a large Milner safe, for the safe-keeping of amalgam and bullion.

The zinc precipitation-boxes, nine in number, are all the same size, namely, 14 ft. long, divided into 10 compartments, 2 by 2 by 1½ ft., fitted with 4-mesh screen false bot tom, to allow the precipitate to accumulate between the screen and the bottom compartment. Each compartment is fitted with a 2-in. wooden plug, inserted in a hole in one corner to facilitate cleaning up, and each box has a launder running the full length of box, to convey the precipitate to a clean-up vat, 4 ft. square by 2 ft. deep. This vat is furnished with a filter cloth on the bottom, and the space beneath the cloth is connected by a pipe to a steel receiver 10 by 3 ft., which is again connected to a small vacuum pump, 6 in. diam. by 9 in. stroke. The solution from the sand and slime treatment is run through the zinc boxes, and into the various sumps, of which there are five, each capable of holding 10 tons of solution. The zinc shaving used is cut at a local foundry, and is dipped in a solution of acetate of lead before being placed in the boxes. Acetate of lead has been found to improve the precipitation when dealing with weak and foul solutions, and, as a rule, the solutions leaving the zinc boxes rarely assay more than 1d. per ton.

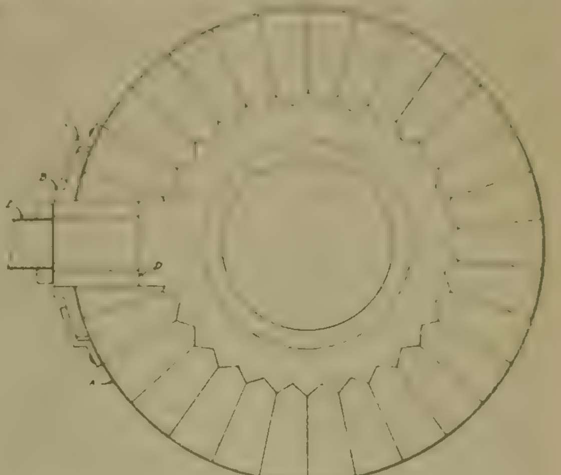
A clean-up is made every four weeks, and the method is as follows: The solution flowing through a box having been shut off, the coarse zinc is shaken and washed in the first, or top cell, and then taken out and placed on a tray. The plug in the bottom of the cell is then removed and the broken zinc, slime, and solution, are run into the clean-up vat, the cell is then sluiced out with a few quarts of solution from one of the other cells, and the plug replaced. The coarse zinc on the tray is replaced in the cell just emptied, and the coarse zinc in the next cell washed and placed with it. The same procedure is adopted with each of the cells in the box, and when all are replenished with zinc shaving, the solution is turned on again, and precipitation proceeds as before. All the time that the slime and short-zinc are running into the clean-up vat a vacuum-pump is taking away the solution and leaving the mixture of short-zinc and bullion slime on the filter-cloth. When fairly dry, a water-wash is put on the filter, and when again dry, the mixture is shoveled into a circular wooden vat, 6 ft. diam. by 2 ft. deep, furnished with stirring gear. A weak solution of sulphuric acid, 10 parts water to 1 part acid, is run on the slime, and the whole stirred until all the short-zinc is dissolved. The whole of the content of the acid vat is then transferred to a second vacuum-filter box, where several water-washes are added, and all the zinc sulphate washed out of the precipitate. The slime is then placed on thin iron trays, 3 ft. square, and taken to the melting-room.



TURN-OVER VACUUM FILTER, KOMATA REEFS.

The melting-room is detached from the main mill building, as the insurance companies do not permit the use of gasoline as a fuel inside insured premises. It is a room 30 by 20 ft., built of iron and wood, with a concrete floor, and ample provision is made for carrying off the gases. The trays of precipitate from the vacuum filter are placed in a drying-furnace made of sheet iron. This furnace is 6 ft. high by 3½ ft. square, and has three openings or shelves for receiving the trays of precipitate; the fire is placed on a grate near the bottom of the furnace, and the flame travels in a zig-zag manner under and over the shelves and escapes into a flue at the top of the furnace. This furnace will dry over 800 lb. of precipitate in 8 hours, wood being used as fuel.

The dried slime is then transferred to a rotary tubular screen, half filled with flints, and there reduced to a fine powder and mixed with borax glass in the proportion of 5 parts slime to 1 part borax glass. The mixture is melted down in plumbago crucibles (Morgan's No. 70), the pots being placed in specially designed furnaces, benzine being used as fuel. The benzine is stored in a tank of 50 cu. ft. capacity, placed on the hillside 70 ft. above the melting room, and conveyed to the melting room by means of ½ in. diam. galvanized pipe. Four furnaces of special shape, designed by me, are used for melting the slime and the resulting bullion is over 900 fine, the proportion of gold to silver being generally about 1 to 8. The bars of bullion are dipped in powdered nitre in order to clean the outside of the bars, and are then polished with a scratch-brush, sampled, and sent to the local bank for shipment. The slag is very clean and is crushed by a single stamp to recover any 'shots' of bullion that may be retained. The crushed slag is re-melted periodically, and the final slag rarely assays more than £4 per ton. The amalgam from the plates is retorted in a horizontal retort, fitted with trays, and the retorted metal is melted down and cast into bars of suitable size and sold to the local bank. The fineness of the bars is about 900, the gold fineness being 600 and the silver 300. The cost of melting is 1.34d. per ounce.



BULLION FURNACE, KOMATA REEFS.

The assay plant is situated a short distance from the mill; the building consists of a sampling room, furnace room, balance room, chemical laboratory, and store-room. The sampling room is furnished with the usual sampling and quartering apparatus, a drying oven is used for drying the samples and evaporating solutions, and there is a sample crusher and grinder driven by a small Pelton wheel. Gasoline furnaces are used, both for fluxing and cupelling. These are made on the premises, and are of better shape than the imported furnaces; they are made by mixing broken crucibles and fire-clay together and ramming into a thin iron frame. After being allowed to dry for some days, they are finally baked into a hard brick. Gasoline under a head of 70 ft., is used in 'Cary' burners; a 1½-in. burner is used for the fluxing furnace. The chemical room is fitted with all the appliances for analysis, testing of ores by cyanide, and other processes, electrolytic experiments, etc., and has in addition to these, a small tube-mill, and four air-agitation tanks, each 18 in. high by 5 in. diam. There is also a small filter in conjunction with this plant, and we are thus enabled to make tests on ore on exactly the same lines as in a working plant.

Oklahoma Metalliferous Minerals

By Charles N. Gould

Oklahoma is extremely rich in mineral products. The chief mineral wealth of the State consists, however, in its non-metalliferous minerals. Of these, the most important are the fuels, including coal, oil, and gas; structural materials including various kinds of building stone, as well as clays, shales, gypsum, and asphalt; and such minerals as salt and others of minor importance. The principal metalliferous minerals known to exist in profitable quantities in Oklahoma are lead, zinc, and iron. Copper, gold, and silver occur also, but, so far as known, not in quantities to justify development.

Lead and zinc occur in two widely separated regions in the State; namely, in the northeastern counties, and in the Arbuckle mountains. In northeastern Oklahoma these metals occur in the same rocks as in the Joplin region, this being the southwestern extension of the Ozark uplift. Small quantities of these metals have been found in Ottawa, Delaware, Adair, Cherokee, and Mayes counties. The chief development has been in the northeastern part of Ottawa county, where there are three well developed camps, known as the Miami, Peoria, and Quapaw. The first mining in this region was done about 1890. At the present time Miami is the most flourishing camp.

In the Miami region the geology is comparatively simple. The surface rock is a black, carbonaceous shale, belonging to the Cherokee formation, and is of Pennsylvanian age. Below this shale there are the sandstones, limestones, and shales of the Chester group. Beneath the Chester group is found the Boone chert. Throughout the productive lead and zinc area a large part of the limestone of the Chester has been removed, probably by underground solution, allowing the insoluble sandstone to settle down on the Boone. In this process of settling, the sandstone has been fractured and broken into angular fragments forming often a brecciated mass. The underground waters carrying the ores in solution have circulated freely in this breccia, and in so doing the ore has been deposited, filling the cracks and crevices and cementing the breccia into a solid mass. Most of the ore so far mined in the district occurs in this manner. There are two other modes of occurrence of the ore in the district; first, as an impregnation of the sandstone itself, and second, as a pure ore mass filling small solution cavities in the limestone. The latter mode of occurrence is relatively rare.

Among the minerals found associated with the orebodies the most important and troublesome to the miners is marcasite. This mineral, being nearly as heavy as the sphalerite, makes separation by jigging difficult, and therefore lowers the grade of the ore, there being a penalty of $1 per unit for iron. Much heavy oil, or bitumen, is found impregnating the rock and the crevices in the same manner as the ore. This oil is also a source of trouble to the miners, as it tends to agglomerate the crushed ore in the jigs, and prevents ready separation. Little or no calcite ('tiff') or dolomite ('spar'), which are so common in the Joplin region, are found with the Miami ores. The ores mined are practically all sphalerite and galena. There is but an insignificant amount of silica or carbonate ore.

The ores are easily mined, and only the most simple methods are employed in raising and separating them from the gangue minerals. The ore is broken by dynamite, and hoisted to the surface in buckets operated by donkey engines. This material is then crushed and the ore separated from the gangue minerals by the use of jigs. This separation is easily effected, owing to the wide difference in the specific gravity of galena and that of the gangue minerals. During the past two years, development has steadily increased, until now there are 25 mines in operation. The production for 1910 was approximately $700,000. The greater part of the zinc concentrate is smelted in Iola, Kansas, and Bartlesville, Oklahoma. Within the past few months there has been considerable prospecting outside the developed field, and there is little reason to doubt that more extensive deposits will eventually come to light.

For a number of years there has been much prospecting for lead and zinc in the Arbuckle mountains of southern Oklahoma, and much time and money has been spent in the attempt to find deposits of value. At the present time there is considerable activity in two localities, near Davis and Ravia, where lead and zinc are reported to occur. A number of carloads of ore have been shipped from Davis to the smelters at Bartlesville, and some of these shipments have proved profitable. Practically all the ore so far obtained in the Arbuckle mountains comes from within a few feet of the surface. A number of shafts, which have reached a depth of 50 ft. or more, have discovered little of value. It is unwise, at the present time, to predict what the future of this region will be.

There are three regions in Oklahoma where considerable deposits of iron ore have been reported, and which may possibly repay investigation; namely, the Wichita mountains, the Arbuckle mountains, and a locality near McAlester. Considerable deposits of high-grade iron ore, chiefly magnetite, occur in the Wichita mountains. Large boulders of this ore are scattered over the surface in several localities, particularly in a region 10 to 15 miles northeast of Mountain Park. No systematic surveys of these deposits have been made, and until this is done there is no way of arriving at an estimate of their value.

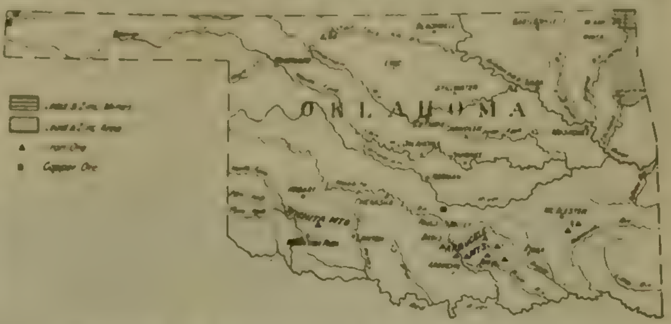
In the Arbuckle mountains there are extensive bodies of iron ore. All these deposits occurred originally in the form of pockets in the limestone. In some cases the ore is still imbedded in the rock, while in other localities the limestone, which is more soluble than the iron ore, has been removed, thus leaving the boulders of iron scattered over the surface. There are dozens of localities in the mountains where there are quantities of the massive black boulders, sometimes as much as ten feet in height. Cases of this kind occur near Davis, Roff, Bromide, Mill Creek, Hunton, Ravia, and Franks. This ore is usually of high grade, some of it being manganese-iron ore, which commands a high price. Shipments of the ore have been made from near Hunton and Mill Creek.

For several years there have been persistent rumors that large deposits of iron ore are to be found in the mountains south of McAlester. It has been stated, on what seems to be good authority, that mining engineers have examined these deposits in the interest of corporations and have made extremely favorable reports. Specimens which I have examined, said to have been obtained from these localities, appear to be rather low-grade iron ore. It is quite probable that the visible iron ore, scattered over the hills in widely separated areas in Oklahoma, aggregates several millions of tons. The greater part of it is in localities difficult of access. With good transportation facilities and the increasing demand for iron ore, it should be a question of but a short time until the Oklahoma ores are developed. Fortunately, both fuel and limestone for flux are abundant near McAlester and the Arbuckle mountains. If iron ore proves to be present in quantities sufficient to justify development, there will be no lack of fuel with which to smelt it.

Copper is widely distributed among the rocks of Oklahoma. There is hardly a county from which it has not been reported. In practically every instance, however, it has been found in such small quantities that it is not of commercial importance. In most cases nothing has been found but the greenish copper stain, but in a number of instances, near Perry, Noble county, and Winnview, Blaine county, for example, small nuggets of native copper the size of a hazelnut occur, scattered through the reddish clay-shale. In some instances tunnels have been driven into the red clay banks for as much as fifty feet, and several gallons of these small copper nuggets have been secured. In no case, however, has the amount of mineral obtained justified the expenditure.

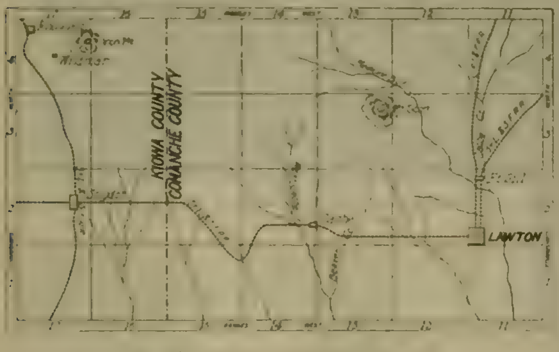
There is a region along the valley of Cimarron river and Carisso creek, near Kenton, in the extreme northwestern corner of the State, where copper was mined for a number of years. Several hundred shafts have been sunk in this region. The rocks, which are redbeds similar to those in central Oklahoma, are in many places vividly stained with copper. Some of the material obtained has been hauled to the railroad and shipped to smelters, but the venture did not prove profitable, and at the present time all of these workings have been abandoned. Copper mines were opened, a number of years ago, in the vicinity of Byars, McClain county, and operated by primitive methods for some time. But they, too, were not profitable, and nothing remains at the seat of operations but a few holes and old tunnels, and a part of an old improvised horse-power crusher, used for pulverizing the ore.

Copper has been reported from Kiamichi mountains, in the southeastern part of the State. There is a region not far from Hochatown, in east central McCurtain county, where small quartz dikes have cut sandstone and shales. Along the contact of these dikes the rock is stained with copper, but it has not been found in marketable quantities. Copper also occurs in small quantities in igneous rocks, in both the Arbuckle and Wichita mountains. A number of shafts have been sunk in each region and considerable amounts of ore taken out. One Government assay has been made which shows 10.81% of copper. It is possible that if a sufficiently large body of ore were developed, and improved methods employed, these mines might be made profitable.



LOCALITIES FOR METALLIFEROUS MINERALS IN OKLAHOMA.

There is a widespread notion that gold and silver occur in profitable quantities in Oklahoma. Much time, money, and effort have been wasted in the hope of finding these metals, but neither gold nor silver from Oklahoma have been placed on the market. There is perhaps not a county in the State in which the precious metals have not been sought. The greater part of the effort, however, has been put forth in the Wichita and Arbuckle mountains. Since the time of the Marcy expedition into this region, in 1852, prospectors and miners have been at work in the Wichitas.



MAP OF WICHITA MOUNTAIN REGION.

It is even claimed that the Spaniards sought gold there, and the sites of old Spanish mines are still pointed out. There is, however, no authentic record that the Spaniards, or anyone else, ever found anything of value.

At the time of the opening of the Kiowa and Comanche country to settlement in 1901, there was much activity in the Wichita mountains. It has been estimated that at one time there were more than 2000 miners at work in the region. The mountains were then bristling with claim notices and honeycombed with mining shafts. Scores of camps were scattered throughout the mountains. According to various estimates, all the way from half a million to a million and a quarter dollars has been spent in sinking shafts in the Wichita mountains. Some of the shafts reached a depth of 200 to 250 ft., although most of them were less than 25 ft. deep. Several small smelters were erected, and a number of carloads of ore were shipped to large smelters at Pueblo and Denver. Hundreds of assays have been published, many of them claiming results as high as several hundreds, or even thousands, of dollars per ton. Several reports have been published by Government and other officials on the occurrence of gold and silver in the Wichitas, the most important of which will be cited.

In 1904 E. G. Woodruff, then professor of mineralogy in the State University of Oklahoma, now a member of the U. S. Geological Survey, spent several weeks in the Wichita mountains, visited practically all the camps then active, and wrote a paper entitled 'Present Status of the Mining Industry in the Wichita Mountains of Oklahoma'. He sums up his conclusions as follows:

"The mining industry of the Wichita mountains is still in the prospecting stage. A conservative estimate places the number of claims located at about two thousand five hundred. On many of these claims no work whatever has been done. It is probable that 500 openings are from 10 to 15 ft. deep. The number of shafts ranging from 20 to 25 ft. deep does not exceed 100. Possibly 50 are more than 30 ft. deep. A few have gone beyond 100 ft., and in one case the shaft was more than 200 ft. deep.

"Two cars of ore have been shipped, one from the Wildman district, and one from the Oreana district. In addition to these shipments, a number of sample shipments have been made. At this time no ore is leaving the region. In one district a small smelter is being constructed to separate the bullion from the gangue.

"A word should be added concerning the damage which unscrupulous assayers have inflicted upon the region. With premeditated purpose they have, in many cases, issued false certificates, thus buoying up hope where it already existed, and creating undue excitement. In many cases the unsuspecting miner has been led to continue his search for the metal in the most impossible places. No one thing has contributed more harm to the industry than have these unprincipled assayers.

"Development is now in a quiescent state. At the time this investigation was made, five prospects were actually sunk, two in the Meers district, two in the Cache district, and one in the Oreana district."

Edwin Debarr, professor of chemistry at the State University of Oklahoma, visited the region during the summer of 1904 and collected 197 samples, which were afterward assayed. Mr. Debarr's conclusions are as follows:

"All samples were assayed by fluxes and by the cyanide processes, and the heavy sulphides were assayed by the chlorination process, and all save No. 136 showed no trace of gold.

"No. 136 was obtained from washing placer material south of Brushy and Bald mountains and Gold Hill, in the creeks and in Deep Red, in which material there is a very small quantity of exceedingly fine gold in a limited area. The lack of water, and the black iron in which it is found, together with the limited amount of gold therein, renders it unprofitable for working.

"No. 94 showed 0.98 oz. of silver and 3.6% of lead. No. 20 contained 5%; No. 21, 3½%; No. 23, 8⅓%; No. 9, 5%; No. 10, 3%, and No. 11, 3½% of copper.

"In collecting and sampling the above ores, the greatest care was taken to secure a good sample free from contamination, and with a view to revealing the true condition of values from the supposed mineral-bearing material. Whenever possible the samples were taken from the shafts."

H. Foster Bain, then a member of the U. S. Geological Survey, visited the region in October 1904, and collected 95 samples, 71 of which were assayed by E. T. Allen, chemist to the Survey. Mr. Allen reported as follows:

"After the usual cupellation and parting, gold was looked for most carefully, but not a trace was found in any of the samples.

"Ten of the above samples were examined for silver, as prescribed for gold, but no silver was found except in No. 41 and 48, which showed 0.14 and 0.92 oz. per ton, respectively.

"No. 57 and 73 were also assayed for copper, and No. 38 for lead. No. 57 gave 0.35% copper; No. 73 gave 10.81% copper; No. 48 yielded 3.63% lead."

Mr. Bain's conclusions are as follows:

"In view of the precaution taken in collecting the samples and the great care with which they were assayed, the absolutely uniform absence of even a trace of gold, and only the occasional presence of a small quantity of silver, copper, or lead, allows but one conclusion to be drawn, namely, that none of the prospects examined show any ore in the proper sense of the term, nor does any one of them have any present or probable future value.

"Whether future prospecting may reveal other occurrences which do have value, cannot, it is true, be stated. It is believed, however, that the prospects examined were fully representative, and have, in many cases at least, been developed enough to allow a proper judgment as to their value to be made, and in no case do they offer any encouragement whatever for additional prospecting."

Very little work has been done in the Wichita mountains during the past six years, and at the present time the greater number of the shafts are filled with water. A few persistent prospectors are still at work, and stock in mining companies is being offered for sale, but there seems to be little promise of renewed activity.

Prospecting in the Arbuckle mountains never reached the stage attained in the Wichitas. The structure of the rocks in the two ranges is practically the same, and there is as much reason to suspect the presence of gold in one as in the other. A number of shafts have been sunk in the Arbuckles. The greater part of them are in the West Timbered Hills, south of old Fort Arbuckle, but so far as is known nothing of value has ever been found. Joseph A. Taff, formerly a member of the U. S. Geological Survey, has studied the problem more carefully than anyone else. In a published report, after reviewing the structure of the region, he concluded:

"All the fault contacts between the igneous and stratified rocks have been carefully traced, but no indication of the mineralization of the rocks or the occurrence of ore deposits of any consequence along them have been noted.

"Many of the dikes, chiefly those of diabase, cutting the granite have been prospected at various times for the precious metals without any show of profit, and the sum of all information obtained gives no assurance that ore or metal deposits of any value can be found in the region."

Local Sections of the A. I. M. E.

The committee of the American Institute of Mining Engineers appointed to consider the advisability of organizing local sections of the Institute, have reported favorably on the project and have formulated the following rules which have been duly adopted. Steps have been taken already to organize sections in New York and San Francisco.

1. A local section of the Institute may be authorized by the council at the written request of ten members residing within an appropriate distance of a central point.

2. Only one section shall be authorized in one locality or district.

3. The council shall define the territory of a section.

4. A section must consist of 25 or more members; when its membership falls below 25 in number the council may annul the section.

5. Only members of the Institute shall be members of its local sections.

6. All members of the Institute, of all grades, residing within the territory of a section shall *ipso facto* constitute the membership of such section.

7. The officers of a section shall be elected after the formation of the section has been duly authorized, at a meeting of the members of the Institute within the territory of said section, called by the sponsors of the section, notice of said meeting and its object being given to said members at least thirty days in advance. Officers shall be elected for a term not longer than one year.

8. The officers of a local section shall be a chairman, vice-chairman, secretary, treasurer (or secretary-treasurer), and such others as the section may desire.

9. Whenever the Institute is financially able to do so, it shall be the policy of its board of directors to contribute from its funds for the legitimate running expenses of each local section an amount not exceeding, in each year, 25% of the dues received from the members of said section in said year. Requests for such appropriations shall be signed by the chairman, secretary, and treasurer of the section.

10. If the expenses of a section exceed the appropriation made it by the Institute, the difference must be made up by voluntary contributions, but not by assessment upon the members of said section. The Institute shall not be responsible for the debts of its sections.

11. The Institute reserves the right to cancel a section, or re-adjust its territory.

12. Papers presented at local sections, and discussions thereon, if reported, are the property of the Institute. They shall be submitted to the publication committee and published in the *Bulletin* or *Transactions*, or both, if approved. Such papers shall not be published elsewhere without permission of the council. The reading of a paper before a local section shall not carry with it the right of publication in the *Bulletin* or *Transactions* of the Institute.

13. Neither the author of a paper presented to a local section nor the local section shall have the right to reprint a paper or publish it in advance of the meeting without obtaining permission of the publication committee of the Institute, which shall determine the details of such permission. Nothing herein shall forbid the abstracting of a paper by the press after its presentation before the local section.

14. The Institute shall print advance copies of papers offered to local sections, in order to facilitate discussion thereon, provided that such papers are approved for such advance publication by the chairman or secretary of the local section and by the publication committee of the Institute.

15. Papers read before a local section may also be offered for reading or discussion at general meetings of the Institute, and shall be given equal standing with the other papers on the program of said meeting, when approved by the publication committee.

16. Each local section shall transmit promptly to the secretary of the Institute full announcement of its proposed meetings, and an abstract of its proceedings, including the names of authors and titles of all papers read before it, for the purpose of preparing a report thereon to be published in the *Bulletin* of the Institute, and for the purpose of enabling the council of the Institute to comply with articles 17 and 19 of these regulations.

17. The by-laws and regulations of local sections shall be subject to the approval of the council.

18. The council reserves the right to amend, annul, or add to these regulations.

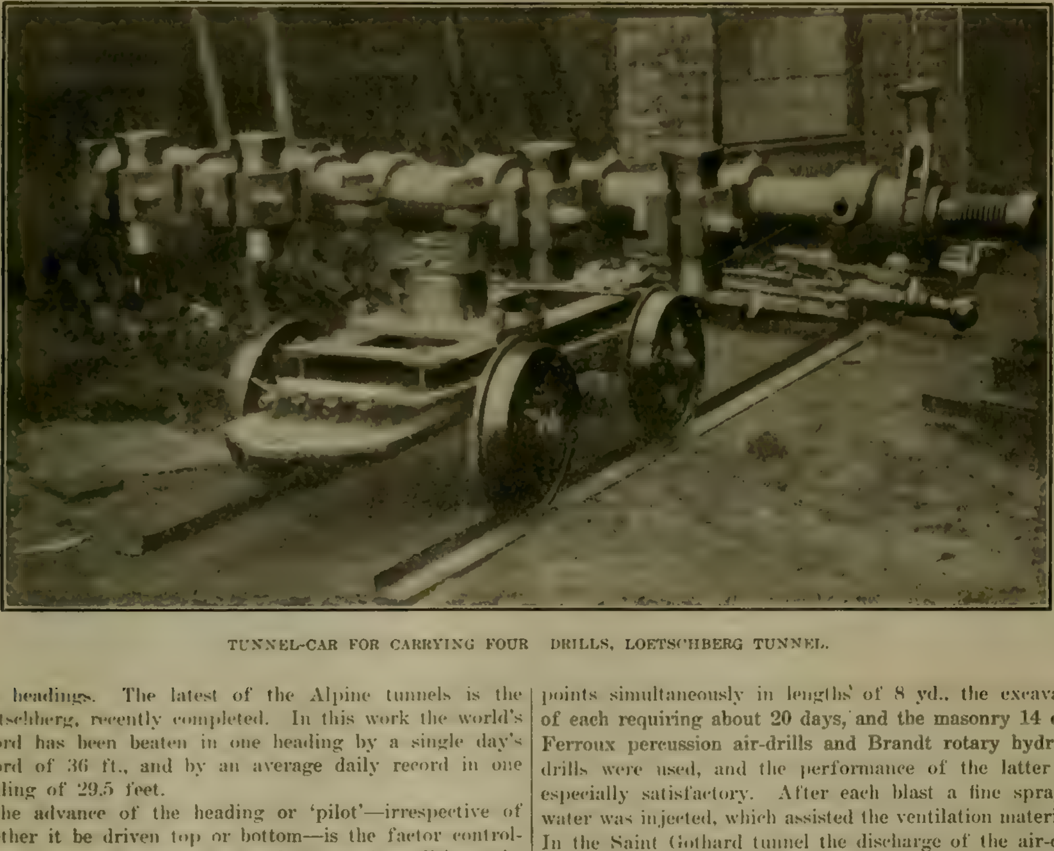
19. No action shall be taken by a section which shall contravene the constitution of this Institute.

It is thus seen that a paper may be presented before a local section, appear in abstract in the local press, and if accepted for publication, be printed in full in the *Bulletin*. This will allow many papers to be presented orally; a difficult proceeding at the regular Institute meetings as now conducted, and one which tends to limit discussion to the few members who are interested enough to write out their views.

Tunnel-Driving in the Alps

By W. L. Saunders

*It is now generally admitted by experts that, at least so far as rapid progress is concerned, the Alpine system of tunnel-driving is superior to any other. These great mountain chains cannot be treated in the ordinary way by shaft sinking and driving headings, thus multiplying the points of attack. The work must be done from the ends only, hence speed in driving is of the utmost importance, and the concentration of effort to make progress has resulted in an organization and in mechanical appliances that have produced results much in advance of the usual practice, even in America. The first Alpine tunnel was the Mount Cenis, length 7.5 miles, driven with a progress that averaged about 7.75 ft. per day. Next came the Saint Gothard, 9.5 miles long, 18 ft. per day; Arlberg, 6.5 miles long, 27.25 ft. per day; Simplon, 12.25 miles long, 36 ft. per day. The figures represent progress when driving from two headings. The latest of the Alpine tunnels is the Loetschberg, recently completed. In this work the world's record has been beaten in one heading by a single day's record of 36 ft., and by an average daily record in one heading of 29.5 feet.



TUNNEL-CAR FOR CARRYING FOUR DRILLS, LOETSCHBERG TUNNEL.

The advance of the heading or 'pilot'—irrespective of whether it be driven top or bottom—is the factor controlling the rate of advance, as, under normal conditions, the enlargement to full size, timbering, and lining, readily keep pace with the advance of the heading. The manner of removing débris in the headings, and the time required to do it, average about the same. The increased average gain in the rate of advance has been concurrent with the improvement in the machinery employed in the headings. Where a great thickness of rock overlies a tunnel, it is necessary to do the work wholly from the two ends, without intermediate shafts. The problem resolves itself into devising the most expeditious way of excavating and removing the rock.

In 1872 the Saint Gothard tunnel was commenced, and in 1881 the first locomotive ran through it. Mechanical drills were used from the commencement. Tunneling was carried on by driving in advance a top-heading about 8 ft. sq., then enlarging this sidewise, and finally sinking the excavation to invert level. Air for working the rock drills was compressed to 7 atmospheres by turbines of about 2000 hp. From 6 to 8 Ferroux drills, making about 180 blows per minute, were mounted on a carriage pushed to the point of attack. From 13 to 18 holes were drilled by the machine and its 16 attendants to depths of from 2 ft. 7 in. to 4 ft. 4 in. in from 3 to 5 hr., and the work of charging with dynamite, firing, and clearing away was then done by 22 men in from 3 to 4 hr. The charge per hole averaged 1.75 lb., and after firing, a strong current of compressed air was directed against the face of the excavation. Four sets of holes were, under favorable circumstances, drilled in 24 hr., which rendered attainable, in each heading, a progress of 13 ft. per day in such rock as gneiss.

The driving of the Arlberg tunnel was commenced in 1880, and the work completed in little more than three years. The main heading was driven along the bottom of the tunnel and shafts were opened up from 25 to 75 yd. apart, from which smaller headings were driven right and left. The tunnel was enlarged to its full section at different points simultaneously in lengths of 8 yd., the excavation of each requiring about 20 days, and the masonry 14 days. Ferroux percussion air-drills and Brandt rotary hydraulic drills were used, and the performance of the latter was especially satisfactory. After each blast a fine spray of water was injected, which assisted the ventilation materially. In the Saint Gothard tunnel the discharge of the air-drills was relied on for ventilation. In the Arlberg tunnel more than 8000 cu. ft. of air per minute was thrown in by ventilators. In long tunnels the quick transport of materials is of equal importance with rapid drilling and blasting. In the Arlberg, to keep pace with the miners, 900 tons of excavated material had to be removed, and 350 tons of masonry to be introduced, daily, at each end of the tunnels, which necessitated the passage of 450 cars. This traffic was carried on over a length of 3.5 miles on a single track of 27-in. gauge with two sidings. When the locomotives ran into the tunnel the fires were damped down, and as the pressure in the boiler was 15 atmospheres, the stored-up heat in the water furnished the necessary power. The cost per linear yard varied according to the thickness of masonry lining and the distance from the mouth of the tunnel. For the first 100 yd. from the entrance the prices per linear yard were £11 8s. for the lower heading; £7 12s. for the upper one; £30 10s. for the unlined tunnel; £45

---

*Abstract of a paper read before the Wilkesbarre Meeting of the Amer. Inst. Min. Eng., and issued subject to revision.

for the tunnel with a thin lining of masonry; and £124 5s. with a lining 3 ft. thick at the arch, 4 ft. at the sides, and 2 ft. 8 in. at the invert.

In 1893 the Jura-Simplon Railway Co. contracted with Brandt, Brandau & Co., of Winterthur, Switzerland, for the construction of a tunnel from Brigue, on the north side, to Iselle, on the Italian side of the Simplon pass, and 12.4 miles in length. The contract time for construction was 5½ years. At the Swiss end the river Rhone was dammed. The power available here was about 2200 horsepower. At the Italian end the power was derived from the Diveria, about 2.5 miles above the works. There was also a supplementary steam-power plant of about 220 hp. The distribution of the power was proportioned about as follows: for high-pressure pumps, 700; for air-compressors, 400; for ventilation, 500; for illumination, 100; for machines in the shops, 100; making a total of 1800 horsepower.

The distance between portals is 12.4 miles, and except for a short curve at each end, the alignment is straight. The work consists of twin single-track tunnels exactly parallel in plan and profile, and lined throughout with masonry. A centre bottom drift was first driven by power drills, and then timbered and covered with a closely boarded roof. From this drift a shaft was driven upward to the roof line every 164 ft. (50 m.). The top heading was then excavated by working in both directions from each of these shafts. Next in order, the floor of the upper headings was removed, and then the two side cheeks of the bottom drift. The lower drift being timbered, no interruption of the traffic in it was caused by the removal of the rock above. The advance drift was the only part of the operation performed by power drills. The drills employed were Brandt rotary machines mounted in groups of two on a heavy thrust bar about 12 inches in diameter. This thrust bar was pivoted to a drill-carriage and was counterbalanced. The section at the heading was nominally 6.5 by 9.5 ft., or 61.75 sq. ft., and as the depth of each blast was roughly 4.5 ft., the material removed by each blast ranged from 265 to 275 cu. ft. The average daily advance was about 16 ft. at the Italian end and from 20 to 21 ft. at the Swiss end. This work was in gneiss. In rock of more friable nature, such as anhydrite or calcium sulphate, an advance of as much as 34 ft. in 24 hr. was made. After each blast, the time required to clean the heading, set the drills, complete the boring, and remove the drill-carriage, was more than an hour. The explosives used were dynamite at the Italian end, and blasting-gelatine at the Swiss end. The dynamite was put up in packages of about 1 lb. in weight; each hole was charged with six cartridges; each blast in the drift, therefore, used from 60 to 66 lb. of powder, or about 6.5 lb. to the cubic yard. Charges were fired by ordinary fuses, cut so as to give an interval between the firing of successive holes; about 15 min. was required after each blast to clear the fumes from the heading. This was accomplished by means of a ventilating pipe running close to the face and the use of a spray of water. The ventilating pipe exhausted about 35 cu. ft. of air per second, and the spray absorbed the sulphurous gases.

The spoil was cleared from the face by one gang while another gang loaded the collected rock into narrow-gauge cars hauled by horses. No machines were used, all the material being handled by manual labor. The work of clearing the heading was rushed to enable the drills to be put to work as soon as possible. To this end the clearing gangs were composed of men who had been previously rested by performing light work only, and only the most skilled and energetic laborers were employed. The majority of the workers were from southern Italy. There were 14 or 15 men at each heading, worked in three shifts daily. Each gang had two horses for each shift. Horses, which cost $1.60 per 8-hr. shift, died off rapidly and were paid for by the tunnel contractors. Other methods of transportation were tried but proved less economical than the use of horses in the advance headings. The horses took the cars to the compressed-air locomotives, and these in turn took them to the steam locomotives, as already described.

The Loetschberg tunnel, driven through the Bernese Alps, in Switzerland, is the last link of a railroad system connecting the city of Berne directly with the village of Brigue, which is situated at the north portal of the Simplon tunnel. The main tunnel is 47,678 ft. long, and was first planned to be on a tangent. After the cave-in of July 23, 1908, it was found necessary to insert a curve of 3600 ft. radius in the tunnel in order to drive through solid rock. The elevation of the north portal is 3940 ft.; of the south portal is 4000 ft.; and the maximum elevation of the tunnel is 14,081 ft. above sea-level. The maximum grade in the tunnel is 7%. Summarizing, the total length of the road is 45.8 miles, of which 36%, or 86,900 ft., is tunnels. Let it be added that, for construction purposes, a narrow-gauge railway had first to be built to reach both portals. On the south side of the tunnel the construction-railway necessitated 38 tunnels, aggregating 18,000 ft. Of the 38 tunnels, 11 only will be part of the permanent road. Beginning at the north portal, the materials penetrated have been calcareous for a distance of about 13,100 ft.; while on the south side, crystalline schist has been found on about 13,000 ft., and granite, forming the central part of the mountain, has been penetrated by both headings. But little water was encountered in the south heading, about 20 gal. per second; while in the north heading, 105 gal. per second necessitated the construction of quite a large-sized drainage ditch. On July 24, 1908, when the main heading had reached a point 1.6 miles from the portal, it struck a cleft filled with sand, gravel, and water. There was a sudden and violent inburst of these materials, which in a few moments filled up the tunnel for a length of 5900 ft., burying 25 workmen and all the drills and other installations beyond hope of recovery. It was then decided to deviate and cross the Gastern valley farther up stream. With 86% of tunnel completed, the maximum rock-temperature recorded has been 91° Fahrenheit.

Driving of the headings was begun on October 1, 1906, for a single-track tunnel, and continued until October 1, 1907, when it was decided to drive a double-track tunnel; 86% of the tunnel had been driven by October 31, 1910, and the 4000 ft. of heading which had been abandoned after the cave-in of 1908 had been regained.

The power-plant for the south heading is driven by electric power. Compressed air for the drills is furnished by three 2-stage Ingersoll-Rand compressors, each having a capacity of 1950 cu. ft. of free air per minute, and a compression of 145 lb. per square inch. They are driven by 400-hp. electric motors. Compressed air for the locomotives is furnished by two 4-stage Ingersoll-Rand compressors, having a capacity of 460 cu. ft. of free air per minute, and a compression of 1760 lb. per square inch. They are driven by 250-hp. electric motors. The power-plant for the north heading is situated in Kandersteg. Electric power is brought from Spiez. Compressed air for the drills is furnished by two units, each consisting of a 2-stage Meyer air-compressor, each having a capacity of 1770 cu. ft. of free air per minute, and a pressure of 117 lb. per square inch. They are belt-driven by 450-hp. electric motors. Compressed air for the locomotives is furnished by two units, each consisting of a 5-stage Meyer high-pressure compressor, with a capacity of 565 cu. ft. of free air per minute, and a pressure of 1760 lb. per square inch. They are belt-driven by a 250-hp. electric motor.

All trains in the tunnel are operated on a regular time schedule, changed from time to time according to the progress of driving. Steam locomotives are used outside, while compressed-air locomotives are run inside of the tunnel. A few mules are still in use in the south bottom-heading. The cars used for spoil are 6 ft. long, 2 ft. 8 in. wide, and 2 ft. deep, the upper edge being 3 ft. 7 in. above the top of the rail. The gauge for all tracks laid in the tunnel is 30 in.; the rails, of from 30 to 40 lb. per yard, being laid on wooden stringers, except in the last 100 ft. of the bottom heading, where portable rails with pressed-steel ties are used. Trains are run in the tunnel at a speed of from 8 to 10 miles per hour. Electric light is used only in that part of the tunnel already lined with masonry and partly completed. Portable acetylene lamps are used throughout the tunnel with a few exceptions only. They are sold to the men by the contractors for the sum of $1. Besides giving a very bright light, these lamps are clean, easily handled, and they do not give out fumes as do oil lamps.

The records made in driving the headings are due to the excellent organization, and to the methods of setting up and taking down the drills. A drill-carriage of simple but efficient design was devised by the contractors. Each carriage carries four or five drills mounted on a horizontal bar pivoted on a vertical arm, and easily swung into position, and jacked into place. The time required to change the machines from the position for transportation to that for drilling and to commence drilling is usually from 6 to 8 minutes. This fact alone shows the superiority of this system of carrying the drills for such work over any other method used up to the present time.

Three kinds of explosives are used. Dynamite, with about 83% nitroglycerine, is mostly used in the headings. Westphalite and cheddite, being more safely handled, are used for enlarging and for small blasts. Great stress is laid on the fact that a high grade explosive breaks the rock into small pieces, not larger than an orange, which enables the mucking to be done with shovels. Firing is done with ordinary fuses. The dynamite cartridges are wrapped with red paper in order to be easily detected in case of a misfire. Dynamite carriers and handlers are provided with red lanterns.

Italian labor is used throughout the work with the exception of some Macedonians lately imported. Mostly Italians from the northern provinces of Italy are employed. A bonus system of payment is used throughout the different kinds of operations. There are three 8-hr. shifts per day. The following wages are paid:

	Daily wages.	Average bonus.	Total.
Drill-foreman	$1.50	$1.10	$2.60
Drill-runners	1.00	0.70	1.70
Muckers	0.80	0.50	1.30
Nippers	0.70	0.30	1.00
Tracklayers	0.80	0.15	0.95
Masons	1.00	0.40	1.40

The width of the finished tunnel section is 28 ft. at the arch springing and 25 ft. at the base of the rail. The arch is semicircular, the crown being 20.7 ft. above the base of rail. A bottom heading of 6.5 by 10 ft. is first driven several hundred feet in advance of the enlargement. Upraises are then driven from 500 to 600 ft. apart, and a top heading started back and forth. The top heading is then enlarged. In the bottom heading the mining operations proceed as follows: The drill-carriage is run forward from its siding close to the face of the heading, passing over 5 by 5 ft. by $^3/_8$-in. steel plates laid on the floor of the heading for a length of about 30 ft. Each plate is provided with 1-in. holes at the corners for each in handling with a pick. The water and air pipes laid on one side of the heading to about 40 ft. from its face are connected with the drill-carriage, and the drilling begins with the top holes. Water sprinkling is frequently done, especially in starting the holes, in order to lay the dust. Without interfering with drilling, shoveling is going on just behind the drill-carriage, and the loaded cars are run back to a siding, where trains of from 20 to 30 cars are formed and hauled out by air locomotives. Drilling being completed in the heading, the drill-carriage is run back to its siding, and the steel plates laid on the floor are covered with a layer of rock about 4 in. thick to prevent deterioration. The bore-holes are then loaded and carefully tamped, and the last man to leave the heading, after firing the fuses, opens the air pipe valve, the escaping air thus creating a cushion of fresh air from the face of the heading back to a certain distance, so that, after blasting, the muckers are able to go to work without delay. A high-grade explosive only is used in the heading, which breaks the rock in small pieces and renders work with shovels easy. The bore-holes, having an average depth of about 4 ft., are started with a 3-in. drill and finished with a 2-in. drill. On account of giving better results, firing is done with fuses, about 4 ft. long, the centre holes being fired first.

Clearing the tunnel proceeds as follows: Two empty cars are run to the heading, the first one being immediately loaded by two or three men shoveling without interruption until the car is fully loaded. This operation is performed in 3 or 4 minutes, which means that 1 cu. yd. is loaded in from 2.5 to 3 minutes. Owing to the manner of drilling and blasting and to the shallow holes, the rock, instead of piling up in front of the face of the heading, is thrown back, and forms a layer over the floor, which enables the track to be cleared rapidly.

Getting rid of broken rock is a problem in tunnel-driving. At Loetschberg a cubic metre car (35.5 cu. ft.) is filled in 5 minutes, and it takes only 1 minute to get this car away and bring an empty car to the heading. In order to do this, small entries or chambers are excavated at intervals in the lateral wall of the main heading, which enable an empty car to be thrown from the track on the side, thus clearing the track and allowing the filled car to pass, whereupon the empty car is turned up on its wheels and rolled into the heading. Drilling is started not more than 5 min. after the removal of the last carload. This result, which at first sight seems impossible, is only obtained by absolute discipline. The rate of drilling is 15 to 16 holes in from 1.1 to 1.15 hours. An engineer who recently visited this work says:

"When I arrived at the heading it was 9:30 a.m. The holes were being prepared for blasting. The blast took place at 9:35 a.m.; 5 min. after the blast the men were in place removing débris, and at a little after 11 a.m. the drill-carriage was in place again and the rock-drills were working. It usually takes from 25 to 30 min. between the time at which the drilling is finished and the time at which the start is made to remove the débris; that is to say, 25 min. for taking away the drill-carriage, cleaning the holes, loading with explosives, and blasting. An additional 5 min. is consumed in getting the smoke away by means of the ventilator, and then the men get to work at the débris. In order to assist the men, a spray of water is discharged near the heading after the blast. This water is brought into the tunnel in a pipe placed within a larger pipe, which insulates it and keeps its temperature from being affected by the temperature of the tunnel."

At one time, when the north heading was making a daily progress in excess of the south heading, the contractors sent some of the drills from the north heading over to the south, thinking that perhaps the difference in progress was due to the drill, but the results were not changed. It seems plain that were it a question of machinery only, the machinery making the greater progress would be used throughout, but the difference appears to be one of natural conditions and of organization.

SHRINKAGE system stoping has many incidental advantages. As employed in the mines along the southern part of the Mother Lode in California, the system permits the accumulation of a large reserve of ore in the stopes, amounting roughly to two-thirds of the rock broken. This is of great advantage in a region such as this where labor supply and water fluctuate. In the summer months when both labor and water are scarce, the mine can be run with only a few men and the mill still kept going steadily. The reserve in the stopes thus regulates the price of labor.

BLUE-PRINTS to be carried into wet mines can be rendered water-proof by the following process. Immerse in melted paraffine until saturated, a number of pieces of an absorbent cloth a foot or more square. When withdrawn and cooled they are ready for use at any time. To apply to a blue-print, spread one of the saturated cloths on a smooth surface, place the dry print on it with a second waxed cloth on top, and iron with a moderately hot flatiron. The paper immediately absorbs paraffine until saturated, and becomes translucent and completely water-proof.

Recent Progress in Slime-Filtration Development

By C. S. Haley

The threatened revolution of the cyanide process from a chemical standpoint by the electrical regeneration of solutions has of late provoked a good deal of discussion, and justly. However, the revolution in the mechanical handling of pulp, solutions, and precipitate in the course of the last few years has perhaps not received that share of the attention of the metallurgical press which is its due; yet it has been no less far-reaching in its effects, although more gradual in its development. Of the different phases of this revolution, perhaps the most marked has been that of the change and development in the methods of handling and treating the more flocculent and troublesome portion of the crushed ore classified as slime. It has been my privilege to operate or assist at the installation of practically all the leading types of slime-filters at present on the market; and the results of an experience extending over ten years, not only in connection with the treatment of gold and silver ores, but also with the same type of work in manufacturing processes, has convinced me that there is still much to be done in connection with this line of work.

Ten years ago the present common types of vacuum-filters were practically unknown in the mining world. The necessity for a treatment of the more flocculent pulp different from the ordinary leaching methods applicable to the heavier sand, was early realized; but the treatment as first applied was cumbrous and unwieldy. The problem of securing agitation presented its difficulties, if the maximum extraction was to be obtained in the minimum of time. However, having expended so much time, power, and chemicals, on the solution of the gold, thereby increasing the amount of capital tied up in the mixed pulp and solution, a greater problem arose in the separation of the dissolved metal from the worthless pulp. It is this problem that I wish to discuss.

The first, and simplest, attempt at the solution of this problem was the ordinary decantation method. After agitation the slime was allowed to settle for as great a length of time as economy permitted, and the clear solution was drained off by decantation pipes or siphons. Various modifications of this process were made, and are still used today in more remote localities; but several grave difficulties arose. The first was the loss of time—a considerable factor. Next came the difficulties introduced in the refining of the product by the almost unavoidable introduction of a certain amount of fine silica into the zinc-boxes. Last, and most important, came the difficulty of giving a good wash to the pulp and the necessity of discharging good gold solution with the waste pulp at the end of the operation. After spending money to get gold into solution, any good engineer regards it as little short of criminal to deliberately throw any portion of that solution away. The decantation process, however, reigned supreme in this country for a considerable time. In Australia the method of separation by pressure was long ago in use; but the cumbrous methods required to clean the presses after filtration were a great drawback. The final introduction of this method into this country was signalized by a remarkably ingenious invention which did away with this objection very completely. This will be taken up later more at length.

In Colorado the introduction of filter-leaves into the slime-tanks was developed into a system of gravity filtration which had its drawbacks. Chief of these was the difficulty of giving a proper wash. A downward-percolating solution will not channel in ordinary sands; but in the case of slime it will not do anything else; and channeling is of course fatal to thorough washing. Further, the time element enters in to too great an extent. However, an ingenious mind conceived the idea of applying a vacuum-pump to these leaves and drawing the gold solution through them, leaving the pulp caked on the outside. Washing was accomplished by lifting the leaves, cake and all, bodily out of the original tank, and into another tank containing barren solution, which, on being drawn through the cake, displaced the gold solution and carried it to the precipitation boxes. A variation of this process, by means of which all the operations were carried on in the one tank, by the introduction of different solutions, brought with it improved vacuum machinery, and was soon made, and, as well as the older process, is now in wide use.

As this process is in general use, it may be well to give a brief résumé of its salient points. The pulp is introduced from the agitator, or stock tank, in a semi-liquid condition. Before the slime has a chance to settle in the filter-tank, a vacuum is applied on the filter-leaves, and gradually increased, its limits depending on the character of the ore and the method of treatment. A cake, varying in thickness from three-quarters of an inch to an inch and a half, is formed on the leaves. The surplus pulp is then returned to the stock tank, and the wash-water introduced. This wash-water is drawn through the cake, displacing the greater part of the dissolved metal which remains in the cake. The number of washes applied is of course also dependent upon local conditions. After the surplus wash-water is drawn off, the cake is discharged by the distending of the leaves from the inside by the introduction of water. The main difficulties left to be overcome by this method were still the time element, and, with the more difficult types of ores, the replacement of dissolved metals. While this type of filter is a vast improvement in both of these respects over its predecessors, it is still imperfect. Furthermore, the clogging of the filter pores by fine silica and lime renders frequent acid washing necessary, and renewal of the filter-leaves imperative. The presence of a chain-block for the repair of the slightest leak is imperative, and time is lost in the discovery and repair of leaks, especially as the filter grows older in use. About four or five years ago a filter was put on the market from Colorado which attempted to wash a mixture of sand and slime by upward percolation. This is merely mentioned to show the vanity of human endeavor.

The introduction into this country of the process of pressure filtration was greatly facilitated by the addition of the sluicing-bar, which did away with the principal objection to the filter-press, in that the cleaning of the press-chambers was automatic and speedy, though in dry countries the amount of water necessary for sluicing may be important. Pressure-filtration gained its greatest favor from the fact that, with its use, agitation, with all its use of power, is not necessary. Instead of bringing the particles of ore into contact with the solution, the solution was forced into close contact with the particles of pulp by means of pressure. The heavy and cumbrous presses, by reason of their cost and the difficulty of transportation, have been one great drawback to the use of this process in regions which are at all inaccessible. Its success where conditions admit of its use has been, on the whole, admirable.

Contemporaneously with the development of this form, a rather ingenious pressure-filter which is in no sense a filter-press, was a good thing which came out of Utah. It consists of a large cylinder resembling in outward appearance a compressed-air receiver mounted at an angle from the horizontal. Mounted on a track inside this cylinder is a set of filter-leaves running longitudinally and decreasing in height, of course, from the centre out. Under pressure of about thirty pounds the solution was forced through these leaves, and came out through nipples in the grate to which the filter-leaves were attached. The cake was rapidly formed on the leaves, and the excess pulp returned to the stock tank when a definite time had elapsed. Wash-water was then introduced, and run through the cake for a definite time. Pressure was held on the cake by means of air when the wash-water was returned, and it was thoroughly aerated, producing a very dry cake. When the cycle was completed (ordinarily in about an hour) the end-gate was opened, and the filter carriage let out on a track by gravity, which overhung the discharge chute. The idea was to discharge the cake by internal pressure of water, or steam, where available, but the cake formed is generally so dry that the operator loses much time in scraping and hosing it off. This filter has the advantages of giving an excellent wash and being simple in its operation, but weighed against this is the necessity of having a man constantly watching it and frequently needing a helper to discharge or re-seal the filter.

This amount of labor necessary in the operation of a filter, as well as the time lost in discharging the cakes, has resulted in many attempts to develop a continuous filter; one which would run by itself and be constantly discharging the pulp. Many solutions of this phase of the problem have been offered in the last few years, with varying success. One type which is coming into wide use on account of its convenience and practicability has recently been developed. This filter consists of a revolving drum, whose spokes are vacuum pipes or compressed air pipes, as occasion demands. This drum is immersed in the pulp nearly to its axle, and a gentle vacuum causes a comparatively thin cake to collect on the outside of the drum, whose canvas surface is protected by wire. The pulp is slightly agitated in the filter tank by means of compressed air, and as the cake forms on the surface of the drum it is lifted out of the tank by the revolution of the latter. As it rises and begins to harden, it passes under a dripping spray of wash-water, which is sucked through the drum surface and washes the thin cake. The cake is carried around until it comes within about three feet of a scraper, when, by an ingenious valve arrangement, the suction in that part of the drum is changed to a pressure. This loosens the cake, the wire protects the filter-cloth from the scraper, and before re-submergence that section of the drum is thoroughly cleaned and ready to take another charge. This filter has lately been imitated in Colorado. The valve action in the California patent is simple; the main difficulty arises in case of stoppage of the filter for any cause, when it is a trifle hard to start. The problem of washing seems to be well handled in this filter, the time element no longer enters, and the filter is automatic in its operation. The repair of leaks is accomplished by slipping a small piece of canvas under the wire. One difficulty, however, remains. In the case of a heavy sliming ore, such as a stephanite type, once the pulp is in a cake form it is next to impossible to give it a perfect wash, as a certain amount of channeling is bound to occur. If the cake could be broken up into its various particles of slime before being submitted to a wash, washed by compressed air, and then gathered together again, a practically perfect wash could be obtained. However, in the different filters that have attempted to handle this problem (most of them of the continuous type) the increased mechanical cost and difficulty have far outweighed the saving effected.

On the whole, the development of slime filtration during the past few years has merely exemplified the extreme quickness of metallurgists in adapting themselves to new conditions imposed upon them by the adoption of new processes of treatment.

Diamonds in Liberia

During the dry season of last year there was considerable work done in the recently discovered gold and diamond fields of Liberia; the result being that diamonds of good quality have been found in several places. The work has been carried on regularly; a number of mining engineers and prospectors have already been engaged and are directing their attention, not toward the alluvial gold-bearing strata, but to the more promising diamond winning. In a recent report it is stated that in the beds of the Jiblong river, and four of its tributary streams, 79 diamonds have been found. In view of the finds in German Southwest Africa this is significant, and it is not at all impossible that new diamond fields may be developed.

Placer Mining in Alaska

By L. H. Thomas

Draw a line from Good News bay on the coast of Bering Sea just south of the mouth of the Kuskokwim, northeast to Indian creek, in the Koyukuk basin, and it will pass through all the newly discovered placer fields of the Kuskokwim, the Iditarod, the older Innoko, Ruby, Gold Hill, Melozi, and the new fields of the Koyukuk country. This is a region more than 600 miles long and from 50 to 150 miles wide, in which pay gravels of great value have been opened at eight separate points.

Gold was found in the Iditarod in 1909, but until the summer of 1910 the region produced nothing but conflicting reports. In August last, however, the gold began to come out, and up to June 1, less than a year, the Seattle assay office credits the new camp with $1,112,316. As some gold from the Guggenheim properties, operated by H. L. Jaffe, went to the Selby smelter on San Francisco bay, and as some dust always comes out which never reaches the local office, and some remains in the camp of its origin, the total production of the Iditarod for the season is no doubt in excess of a million and a quarter. Estimates for this season's output exceed five million dollars.

Gold was found in the Innoko in 1906, on Ganes creek, and later on Little and Ophir creeks. In 1907 $13,100 was taken out, and in 1908 the total was $72,100. The next year, 1909, production jumped to $200,000, but nothing so good has been done since. Up to date all mining there has been done by crude methods, though Ganes creek has much gravel that would pay to mine even with steam scrapers, and there is ground which is adapted to the use of steam-shovels.

MAP OF ALASKA.

The Tuluksak discoveries should also be mentioned, where a handful of men mining with rockers took out several hundred ounces of coarse gold as early as 1908, and which has been producing since. The stream comes into the Kuskokwim a short distance above Bethel on the east side. It is easily reached, or will be now that regular transportation has been established on the Kuskokwim.

Gold Hill has been producing for several years, and so have Ruby and the Melozi and the Koyukuk, but last winter's discoveries in the latter region, Indian creek, gives the Koyukuk added importance as a future placer mining region of the North.

The report has come from Ruby of a stampede there, on June 1, near the mouth of Ruby creek, and the establishment of a new town, in which there were 300 tents and one log building. The cause of the stampede was the discovery of gold, as high as a dollar a foot and over, on bedrock just over the Ruby creek divide on branches of the Solatna. This divide is low and Ruby city on the Yukon is but a few miles distant from the new finds. Pay has been found over a distance of some miles, and in places it is a thousand feet wide. One report predicts that 3000 men will be in this new camp before the end of summer, as it is easily reached by steamer from either upper, middle, or lower Yukon points.

These new fields are no places for men lacking in money, physical prowess, and knowledge of mining conditions and mining methods. All such are doomed almost inevitably to failure at the outset, and would better remain away. To the adventure-loving, red-blooded, not-afraid, self-reliant kind of men, the field is inviting and the promise alluring; for the battle is in the open with the odds on the side of the man of courage and endurance.

Goldfield Consolidated Report

In his report for May, J. F. Thorn, general superintendent, gives the following figures: The total production for May was 29,450 tons, containing $962,110, or an average of $32.67 per ton, of which 29,410 tons were milled with an average extraction of 94.51%, and 40 tons were shipped, of an average value of $54.56 per ton; the net recovery from all ore being $30.89 per ton. The total net profit was $679,537, or $23.07 per ton. During the month of May 4585 ft. of development work was performed.

The total cost of mining, development, milling, office, and general expense was $7.82 per ton, distributed as follows:

Mining:		
Development	$1.17	
Stoping	2.17	
		$3.34
Transportation		9.08
Milling		2.26
Marketing		1.13
General expense		0.62
Bullion tax		0.39
Marketing ore shipped		0.01
Construction		0.04
Total cost per ton		$7.87
Miscellaneous earnings		0.05
Net cost per ton		$7.28

During the month the drift on the second level of the Combination mine was extended 50 ft. west through ore that averaged $60 per ton. This will connect with the 136-stope, making an orebody over 100 ft. long. The 354-sill floor in the Mohawk mine was considerably extended, and produced 1647 tons of ore that averaged $30 per ton.

In the Clermont mine the 413 intermediate drift, between the 600-ft. level and 700-ft. level, was advanced about 75 ft., and produced 682 tons of ore that averaged $125 per ton. The raise through the 604 orebody on the 1000-ft. level was connected with the 900-ft. level during the month, and a stope is being started on the 900-ft. level, which has produced 150 tons of $50 ore. The raise from the 1200-ft. level was connected with the winze from the 100-ft. level, the greater part of the winze being in ore of milling grade. The raise, however, encountered no ore of any value. Intermediate drifts are being driven from the bottom of the winze about 120 ft. on the incline from the 1000-ft. level.

Bingham and Garfield Railroad

The Utah Copper Co. has had so much delay and trouble over shipment of ore from its mines to the mills at Garfield that an entirely new railroad has been built exclusively for this traffic. The line runs high along the mountains and is arranged so that trains of 40 cars of 60 tons each may be hauled by one locomotive direct from mine to mill. In addition, the thirty miles or more of track in the company's mines has been turned over to the railway, a subsidiary corporation. The road will be ready for service in July. The following details regarding it are given in the annual report of the copper company.

The road, from a connection with the San Pedro, Los Angeles & Salt Lake railroad near the town of Garfield, to the Magna plant, is about 2½ miles long. The total length of line from the Garfield connection to the auxiliary yards at the Utah Copper Co.'s mines is 20.1 miles. The line between Garfield and the Magna plant is laid with 65-lb. steel, and the remainder of it with 90-lb. steel. The maximum gradient is 2½%, this grade prevailing for about 14 miles. The maximum curvature is 10 degrees, but there are only two curves of this character. There are four 8-degree curves, and the remainder of the curves are 6 degrees or less. The total length of tunneling on the line is 4795 ft., in four tunnels of the following lengths: 682, 754, 2079, and 1280 ft. There are three steel bridges on the upper end of the line, one across Carr Fork, adjacent to the main delivery yards of the Utah Copper Co., having a length of 690 ft., and a maximum height of 190 ft. The bridge across Markham gulch is 640 ft. long and 220 ft. high, and the Dry Fork bridge, about three miles from the upper end of the line, is 670 ft. long and 185 ft. high. The road will be operated, in so far as ore service is concerned, using the heaviest type of Mallet compound locomotives and steel ore-cars of a capacity of 120,000 pounds. This road is approximately ten miles shorter than the line over which the ores are now being delivered. It will do a general passenger and freight business, including the transportation of ores from the numerous mines at Bingham, to the smelters in Salt Lake valley.

Traction Haulage

Oil is used for fuel at the Kennedy and other mines at Jackson, California. It was formerly hauled from Ione, at the end of a Southern Pacific branch, to the various mines in tank wagons, of which one is illustrated below. These wagons were hauled by traction engines. The engine shown in the figure is connected with the boiler ahead and is used on hills where extra motive power was required. One tractor thus hauls 192 bbl. of oil over a mountain road with heavy grades. The rate per barrel was 50c., the distance being approximately twelve miles. Concentrate was taken on the return trip at $1 per ton. At these prices the contractor did so well that a railway was built from Ione to Martel, within a mile of the principal mines. From this point oil is now delivered to the Kennedy mine through a 6-in. pipe-line, 5000 ft. long. In summer the oil flows by gravity, but in winter must be pumped. For that purpose a pump is placed at the railway terminal, being driven by compressed air delivered through a 2-in. line from the mine plant. This saves 16c. per barrel on the old rate and the line has paid for itself several times over.

TRACTION HAULAGE, SUPPLEMENTARY ENGINE.

Suitable roads are required for traction haulage, and the degree of hardness of the road is much the most important. In a soft road the heavy load upon the wheels causes them to make a heavy rut; if the depth of the rut is 4 in., then the traction engine is practically climbing up a perpetual 4-in. ledge. On a hard road little difficulty is experienced, providing the grades are not too steep and the bridges strong enough.

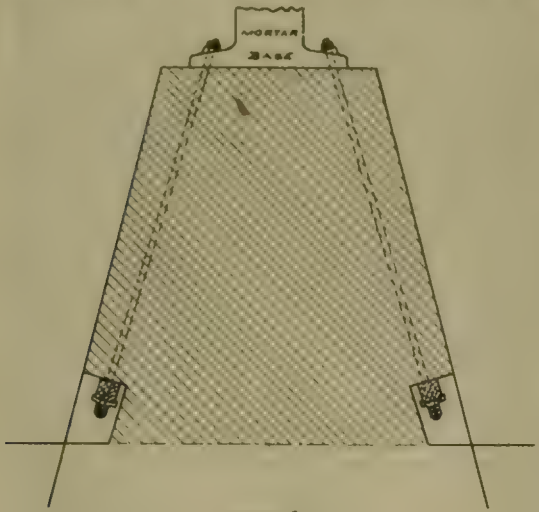
Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Battery Foundations

The Editor:

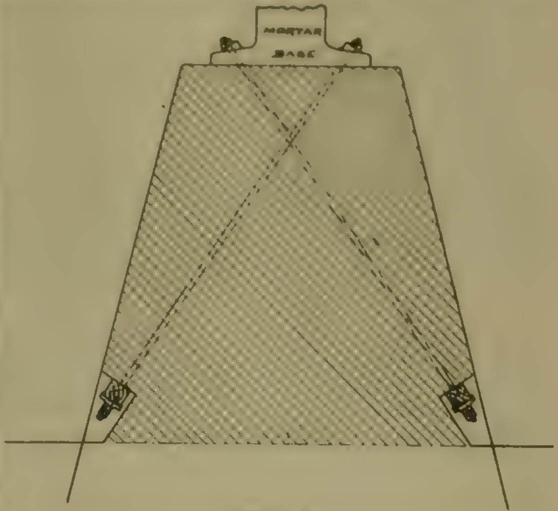
Sir—What is the best form of battery foundation assuming that some form of concrete block is to be used? I have been comparing forms recently built or planned, and find there is considerable difference as well as divergence of opinion among engineers as to the advantages of each form. Form No. 1 shown below, is essentially that in use at the Goldfield Consolidated, the Nevada Hills, the Mother Lode (British Columbia), and perhaps other mines. It is sometimes spoken of as the 'Fraser & Chalmers' design. Why, I do not know. In this form, as in all the others, a pipe is bedded in the cement and the bolts are placed in this pipe so that broken bolts may be easily replaced. There are nuts at each end. At the upper end an iron washer brings the nut snug against the mortar base. At the lower end a woden beam placed lengthwise of the battery distributes the stress and by its compressibility permits the bolt to be kept tight. This form works well in practice. It is simple and easily built, there being no hollow space in the concrete block, the strength of the latter is not impaired, and reinforcement of the concrete is not necessary. Where old cable or iron rods are available some reinforcement is, however, occasionally used. The disadvantages of this form are that renewal of broken rods is awkward. Owing to the shape of a mortar it is necessary to lift it off the block whenever a new rod is placed. It will be noted, too, that the mortars are tied not to the main body of the block, but to what amounts to a ledge or heavy cornice on each side. So far as I know, nonetheless there have been no failures in practice; perhaps some of your readers can inform me.



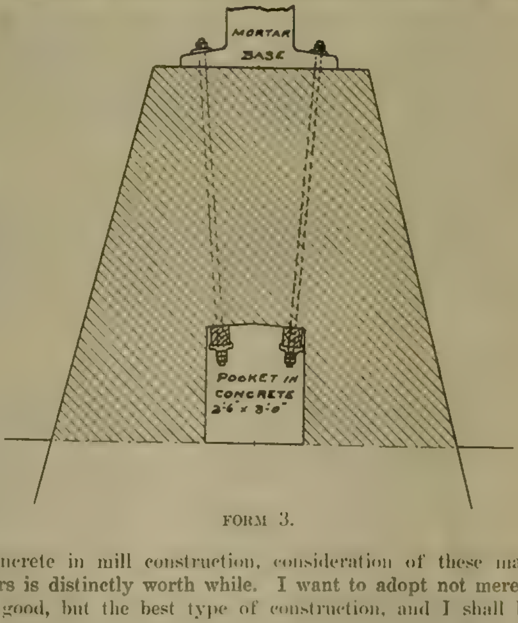
FORM 1.

To obviate the difficulties noted, Form 2 was designed, and it was reported that this form was to be used both at Goldfield and Nevada Hills. I understand that it was given up in each instance. It was, however, adopted for the Santa Gertrudis mill and is being built there. In Form 2 the bolts cross through the foundation. This attaches the mortar securely to the whole block of concrete and it also makes it possible to replace rods without lifting the mortar. The objection urged against this form is the danger of a rocking motion developing. Personally I am unable to see why this should be and I am attracted to this design. Has anyone had experience with it?

The third form has been adopted at a number of mills in Mexico. J. R. Long built it at the Alvarado Consolidated Palmillo mill, and it is also being put in at the Hollinger mine at Porcupine, Canada. It has the advantage that the mortar is securely anchored to the centre of the block, no rocking motion is possible, and bolts may be replaced often, though not, apparently, always, without lifting the mortar. It has the disadvantage that either more concrete or some reinforcement is necessary in order to build an arch which is as strong as the solid block of the other forms. The men who are using this form are entirely satisfied, but apparently experience with it has been too brief to determine what objections, if any, will develop. In view of the increased capacity of stamps set on concrete blocks and the widespread tendency to use concrete in mill construction, consideration of these matters is distinctly worth while. I want to adopt not merely a good, but the best type of construction, and I shall be very grateful therefore if some of your readers will give the benefit of their experience in the matter.



FORM 2.



FORM 3.

PUZZLED ENGINEER.

San Francisco, June 14.

The total quantity of portland, natural, and puzzolan cements produced in the United States during 1910 was 76,934,675 bbl., valued at $68,052,771. Compared with 1909, when the production was 66,689,715 bbl., valued at $53,610,563, the year 1910 showed an increase of 10,244,960 bbl., or 15.3% in quantity, and of $14,442,208, or 26.9% in value.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IRON PIPES may be fully protected from rust for an unlimited period, by coating them with tar and filling them with light wood sawdust, which is set afire. A second coat is not necessary.

RUTILE in the powdered form, when mixed with powdered aluminum and ignited, gives an intense heat with the resulting production of ferro-titanium and alumina. It may be used to convert cast iron into titanium steel.

CRACKED vessels of glass or porcelain, for use in keeping acids, may be made tight by applying a cement made in the following manner: Take finely sifted sand, asbestos with short fibre, a little magnesia, and add enough concentrated water-glass to obtain a readily kneadable mass. The acid renders the putty firm and water-proof.

ELECTRIC FURNACES are used for copper smelting in Norway, where a 1000-hp. furnace is now in use, which is expected to produce 2000 tons per year, and a larger furnace, of 9000 tons per year capacity, is expected to start during this year. Another company is about to start the electric smelting and refining of nickel.

ROPES made of flax and hemp may be protected from rot by leaving them for four days in a solution of copper sulphate, 20 parts by weight to a litre, then allow them to dry, and then, to prevent the copper sulphate being washed away by the water, place in tar or a solution of soap—1 to 10. In the latter case an insoluble copper soap is formed.

CELLULOID can be rendered non-inflammable by denitrating it. A recent method which prevents shrinkage and deformation consists in digesting it with a suitable solution of ammonium sulphide, ammonia, and gelatin, under pressure. The gelatin replaces the nitro-derivatives thus extracted, preventing shrinkage. The gelatin is subsequently rendered insoluble.

WHERE water has been originally appropriated for hydraulic mining purposes and has not been used for such mining for more than five years, but has, nevertheless, been devoted by the claimant to some other beneficial use during said period, the title to said right is still alive. Change of character of use does not defeat water rights which have become vested prior to such changes.

WATER when used for driving hoisting engines introduces a number of troublesome problems, because power must be frequently shut off quickly and water is incompressible. The simplest means of meeting the difficulty is to attach to the water line near the wheel, a boiler or other steel shell into which the water can surge when necessary, compressing the air trapped at the top.

MONEL METAL is a nickel-copper alloy containing about 68% of nickel and a little iron, and has the non-corrosive properties of copper together with nearly the strength of steel. It is especially useful for pumps in mines, for ships' propellers, and for roofing material. It also retains its strength well at high temperatures, which has led to its adoption for locomotive firebox construction.

MANGANESE is best detected by its reaction when fused with soda before the blowpipe. Small amounts of a substance containing manganese, when dissolved in the soda bead, make it opaque and of a green color when cold. A little nitrate of soda will aid in bringing out the color, which may be obscured if too much of the substance to be tested is used, as this test is a delicate one. If a hot borax bead containing manganese is touched to a crystal of nitrate of soda, a rose-colored froth is formed. This is a useful test to corroborate the preceding one.

AIR-RECEIVERS of ample capacity are of benefit in that they equalize the load, and old boilers and tanks may frequently be connected with the system to advantage. At the Eagle-Shawmut mine a whole battery of boilers is now put to this use. At the Utica mine the manager, F. J. Martin, has an unusually large amount of air stored in the mine. This he accomplished by the simple means of bulkheading an old drift with concrete stoppings, and storing the air in it. The drift is 125 ft. long and of the usual cross-section. Being in solid rock, there has been no trouble from leakage.

STAMPS set on concrete have a larger capacity than when set on wood. This may amount to as much as 20% or even more. At the Harvard mine 30 stamps are set on wood and 30 on concrete. The latter are on anvil blocks with a single sheet of rubber belt between the concrete and the anvil block. The concrete block upon which they stand weighs approximately 300 tons. All the stamps are of the same weight (1000 lb.) and are fed with the same ore, crushing through the same screens (20 mesh). The 30 that rest on concrete crush 10 to 14 tons per day more than do the 30 on wood.

ALUMINUM is one of the most malleable of all metals. Moreover, it takes and retains a very high polish. For these reasons it is used in connection with the manufacture of articles of everyday use almost without limit. Some of these new uses are as wall 'paper,' ceiling panels, stamped or hammered trays, and finger-plates, in the form of very thin sheets as a substitute for lithographic stones and zinc plates; and in the panels of car and carriage bodies. The advantages of aluminum in the manufacture of cooking utensils is well known; among these advantages are long life, non-corrosion from acids, and lightness.

TWO TRACTS of land, A and B, are owned by the same person. He also owns a ditch which diverts water from a stream on tract A, the ditch conveying the water from tract A onto tract B where it is used. The owner sells tract A and his deed contains no reservation of the right to take the water out of the stream and convey it through the ditch and off of tract A. A question at once arises whether the original owner can continue to divert the water through the ditch, in view of the fact that he has conveyed the land it crosses without reserving such right in his deed to another. The authorities hold that he can, provided the ditch was in use at the time of the sale, and that no specific reservation is necessary. The purchaser takes the property burdened with all lawful easements which exist upon it at the time he acquires title. He is bound to take notice of the conditions visible at the time of his purchase.

BATTERY SCREENS rarely wear uniformly. In many mills they break first at the bottom immediately above the edge of the frame. Many devices have been tried to remedy this. In some mills the screen cloth is cut extra width and after it has worn at the bottom the screen is torn off, reversed, and refastened to the frame. This brings an unworn part at the place of greatest wear. It is difficult, however, to detach wire cloth, without tearing, after it has once been nailed to a frame, and various screen locking devices have therefore been invented. These consist essentially of a false frame setting down over the screen and wedged into place. One such device, an excellent one, invented by R. E. L. Lampson at the Harvard mill, is manufactured at Angels, but any good mill-man can make one that will serve his purpose. In places where the heavy wear is in the middle of the screen, a protective sheet of coarse wire netting may be placed inside the regular screen. This protects the latter from being hit by heavy pieces of rock and does not greatly reduce the capacity.

Special Correspondence

JOHANNESBURG, TRANSVAAL

Economies in Rand Working Cost.—Relation Between Cost and Grade.—Generalization Not Possible.—Effect of Fine on Crushing.—Rand Geology.

The paper recently read before one of the local mining institutes on 'Future Economies in Rand Reduction Plants' will not be allowed to pass without provoking considerable discussion, and expressions of opposite views. In the first place, the general statement that the cost of mining on the Rand must be expected to increase six pence per ton for every additional thousand feet in depth, and that the value of the ore on these fields is everywhere falling as greater depths are attained, cannot be said to be borne out by facts. The mining cost on the Rand has, as a matter of fact, fallen of late as working depths have increased, but this reduction in working cost has been obtained at the expense of the grade. It has been a general rule on the Rand, with only one or two startling exceptions, that high grade has been synonymous with high cost. If the cost is to be reduced, the reduction must be made at the expense of the grade. Lately some mines like the Robinson Deep and the Village Main have been raising their grade at the expense of higher working cost per ton, but the result has been higher aggregate profits. There are so many different conditions to take into consideration at the different mines here that the working cost can scarcely be regarded as affording any reliable criterion as to the efficiency or economy of either the working or management of any individual mine. Nor will the same policy of mining be applicable in every instance, because the handling of each mine to the best advantage will depend upon the individual circumstances of the mine. There is, however, much justification for the view that it will be only when the huge local mine amalgamations get into proper swing that mining proper will have commenced, and with the large scale of operations the mining and reduction cost is sure to be brought down to the neighborhood of ten shillings per ton. No doubt, as a result of increased depth, mining operations must be more expensive, but no definite increase can be fixed upon, as stated in the paper. The improved mining methods now being introduced must make for lower working costs in spite of the greater depth attained.

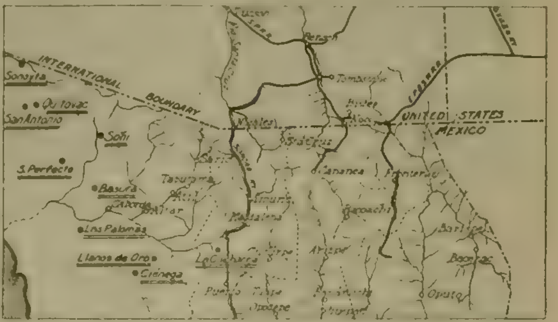
Then again, a member of the Mines Trials Committee of the Chamber of Mines disputes the statement that by taking the fine direct to the tube-mills without passing through the battery the cost of treatment will be reduced, either in capital outlay or operating costs, as it is urged that the absence of the fine does not enable the stamps to crush an increased quantity of ore. Experiments made at the New Kleinfontein mine tend to show that the reverse is the case. The same authority points out that it is possible that in some instances on the Rand second-stage crushing may be carried on to such an extent as to adversely affect the extraction, despite the additional cost incurred, and compares the results obtained at the New Kleinfontein, where there are no tube-mills employed, with the results obtained at the East Rand Proprietary Mines, where he considers tube-milling may possibly be carried to excess. It is clear that the paper will give rise to considerable discussion in mining and metallurgical circles here, and despite the evident traces it bears of hasty preparation can not help but do good by causing some further reflection to be made on the rapid and marked changes now in progress in the metallurgy of the Rand gold mines.

The author of that well-known work, the 'Mines of the Transvaal,' has been writing a series of articles on mining subjects for one of the Johannesburg newspapers. There can be no doubt of the ability of the writer to present his facts to his readers in a very readable and interesting manner, but these articles would seem to show that he is more of a tenderfoot in mining matters than his excellent book would lead one to believe, judging from the numerous blunders these articles contain. The last article written questioning whether the Van Ryn reef, on the East Rand, really belongs to the Main Reef Series, shows such a lamentable ignorance of well established geological facts that locally the article will be read with considerable amazement. He questions the identity of the reef on the Blue Sky mine with that of the Cason, being apparently oblivious of the fact that underground operations have conclusively proved that the reefs are undoubtedly one and the same. Then, with regard to the Van Ryn reef not being contemporaneous with the Main Reef Series, its connection has been traced all the way from Van Ryn to the Cason. In the Far East section of the Rand itself every underlying reef and underlying indication that the Van Ryn reef is nothing more nor less than the Main Reef Series exists, while the attempts to show that the Dupreez Series is a continuous series throughout the Rand, as the author of 'Mines of the Transvaal' does in this article, is directly at variance with the views of the Government Geological Survey, the members of which are now busily engaged in making a geological survey of the Rand goldfields.

MEXICO

Reopening of Railroad Communication.—Shipments Resumed.—New Smelters in Sonora.—Moctezuma Production.—New Properties of Esperanza, Ltd.—Suspension of Power Plant.

Railroad communication between Cananea and the United States was reëstablished after the signing of peace, and operations now are proceeding as usual. The burning of bridges in May left the camp without shipping facilities during a portion of that month but the Cananea Consolidated (Greene-Cananea) had sufficient supplies of fuel oil and coke to prevent a shut-down. The concentrate of the Miami Copper Co., which is being smelted at Cananea, was held at Naco during the tie-up. Supplies for the Cananea Consolidated accumulated at the border, and were rushed into Cananea as soon as the railroad damage was repaired. In the Sierra de Cobre property, purchased by the Greene-Cananea from the Phelps-Dodge interests, a 40-ft. vein was recently opened, and ore running as high as 5% copper and 100 oz. silver per ton is being taken out. The Henrietta mine, closed last year when it was decided to curtail production, has been reopened.



NORTHERN PORTION OF SONORA.

The Sonora Copper Smelting Co. and the Cobriza Mining Co. will shortly blow-in copper smelters in the Magdalena district of Sonora. Both companies have been carrying on development for several years, and both report extensive ore supplies. The plant of this company was built under a State concession providing for important tax exemptions for a period of 20 years. The company plans later to erect a concentrator, and to increase the smelting capacity from 100 to 500 tons daily.

In the first five months of this year the Moctezuma Copper Co. (Phelps-Dodge), operating the Pilares mine and concentrator at Nacozari, Sonora, had a production of 10,456,929 lb. of copper. In the corresponding period of

1910 the production was 9,911,608 lb. The company started the year with a production in January of 1,738,429 lb., and each succeeding month has shown an increase. This year's production is expected to be considerably in excess of that of 1910.

That the Esperanza, Ltd., the English company controlling the Esperanza gold mine in the El Oro district of the State of Mexico, is looking for another property is disclosed by the report of the company's consulting engineer. He states that during the past year no less than 29 properties were investigated, but none was considered sufficiently promising to be taken over. While it is denied that the end of the Esperanza is in sight, it is stated that the company is anxious to secure a mine that will be a guarantee of many more years of successful operation. At the end of 1910 there was an increase of 140,000 tons in the Esperanza ore reserve, the estimated total being 367,000 tons. Since organization, 7½ years ago, Esperanza has paid in dividends £2,229,000, equal to 490 per cent.

As a result of depredations committed by armed men, calling themselves revolutionists, at Salinas, State of San Luis Potosi, the power plant there was put out of commission, depriving the Salinas of Mexico, Ltd., and the Benito Juarez Mines Co. of power and forcing a suspension of work. The Salinas of Mexico is an English company controlling the principal salt enterprises of Mexico, and carrying on extensive operations at Salinas. The Benito Juarez company is a Los Angeles concern, operating several mines and a reduction plant. The mine workings have been flooded since the cutting off of power, and considerable damage has resulted.

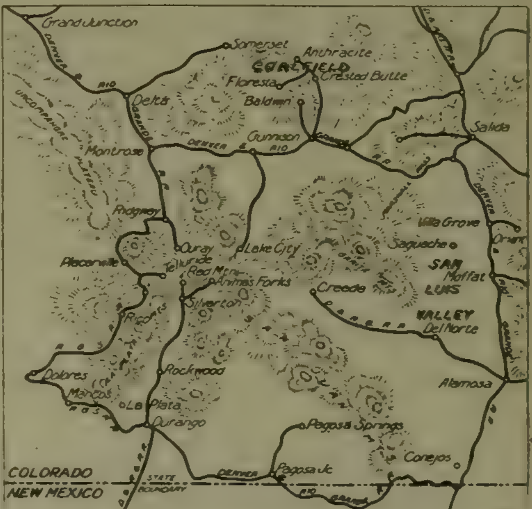
SILVERTON, COLORADO

Examinations of Peerless San Juan, Kittimac, and Tom Moore.—Vermillion Resumes Shipments.—Gold King Reduces Force.—Iowa Mill Temporarily Closed.—Silver Ledge Examined.—Pride of West Shipping.—Congress Sale.

Little new capital has been invested in this district this year, but several important deals are pending. The Peerless San Juan is being examined in the interest of an Eastern leasing company, and the Kittimac and Tom Moore have been examined by an agent of the A. S. & R. Co. The results of these examinations have not been made public. The Silverton railroad was opened to Animas Forks early in June, and the Vermillion mine resumed shipments of concentrate June 15. The mill has been running six weeks and the company has nearly 500 tons of concentrate stored in the bins. The products are lead and zinc concentrate, the former going to Durango, and the latter to Blende. The mill has a daily capacity of 75 tons of ore and the mine is reported to have 50,000 tons of ore available. The Sunnyside at Eureka is planning extensive development work and continues its average production. The Gold King closed down May 27 and resumed operations June 7 with a reduced force, at present employing 50 men and operating 40 of the 80 stamps in the mill. The company found operations on the scale originally planned impossible because of an inadequate ore supply. The ore available at present is low grade, and the property can only with the best management and engineering hope to show a profit. The mine is being operated under lease, and the leasing company seems to be suffering from a lack of sufficient funds to carry out the development required.

The Silver Lake lease has been forfeited by the lessees, because of the refusal of the company to grant certain modifications. It is rumored that the property will be operated on company account, although this seems unlikely in view of the history of the mine and the fact that the company closed it several years ago. Since then there has been no new development that would cause the company to regard the project with favor. The Iowa mill closed June 15 because of a low supply of ore in the mine. The lessees immediately started development on a large scale, and as they are driving toward orebodies that were extensive in all the levels above, it is believed that their efforts will succeed. The plan is to resume milling in July, when it is thought that the ore supply will be ample. The Intersection Leasing Co. cancelled the lease on this mine June 7, and the owners have decided to close the property indefinitely. The Hercules is still idle, but Mr. Kane, the manager, has been in Silverton two weeks and an early resumption is looked for. The Silver Ledge was examined in May for the Chicago lessees. A meeting of stockholders has been called June 24 to discuss means of raising money to liquidate the present indebtedness, and provide for the payment of the purchase price. The property is under bond and lease and the present operators have controlled the mine for two years, and have invested $100,000 in development work, but have never made a payment on the original price of $125,000.

The Danville company, operating the Trilby mine, has a force of six men engaged in cleaning up and putting the property in condition for active work. The Pride of the West has shipped two cars of ore and reports some good ore. The management expects to ship steadily during the summer. A deal is pending for the sale of the Congress, one of the well known Red Mountain mines, and the owners are at present in Denver on business connected with the transfer. Should the property change hands it will probably become an important producer. It has produced ore of a gross value of $500,000, and is down 200 ft. from the surface. The shaft has been sunk to the 400-ft. level and a cross-cut run toward the ore-shoot or chimney. This work is within 50 ft. of the ore, and if, when cut, the chimney shows the same richness as above, the mine will have a good future.



MAP OF SOUTHWESTERN COLORADO.

The lien law mentioned last month has been vetoed by the Governor. The Denver Chamber of Commerce and the newspapers have started a campaign to encourage prospecting. A sum of money has already been subscribed for a grubstake fund. As there is an immense amount of unexplored territory in the San Juan this district offers an excellent field for the prospector, and it is likely that some of the fund will be expended there. The railroad and smelter have reduced rates on all ores shipped and treated of a gross value of $15 or less. As this ore can hardly be shipped at a profit, except under the most favorable conditions, this reduction will be of little benefit, although every step in this direction is encouraging. A substantial reduction on ores from $30 to $50 would be of great benefit, but the railroads and smelters can not afford it under present conditions. Neither is there much prospect of local smelters, which would do away with long hauls, being of much assistance, for their working costs are so high that they cannot be operated at a profit.

SALT LAKE, UTAH

Hopeful Views of the Copper Situation. Increased Production of Lead Ore. Progress near Bingham. New Development in Park City District.

John D. Ryan, president of the Amalgamated Copper Co., has joined the chorus of officials of copper producing companies predicting higher prices for copper. While in Salt Lake on a visit to the Tooele plant, Mr. Ryan gave out an interview in which he predicted a steady advance in copper prices, with a better market than has existed for four years. He said that the consumption at home and abroad is increasing more rapidly than the production is likely to grow, and that the visible supply, together with stocks in consumers' hands, will continue to diminish. D. C. Jackling, general manager of the Utah Copper, Nevada Consolidated, Ray, and Chino, is also optimistic. He declares that the metal will sell at 13c. within two months. Mr. Ryan further said the company intended to make a special effort to encourage the production of lead ores. The International company is making an active campaign for lead ores. It recently made a contract for 70 tons of concentrate per day from the Hecla mine in the Coeur d'Alene district, and for some time it has been piling up ore and concentrate from the Daly-Judge mine in Park City, and accumulating ores from other properties. It is expected that the lead furnaces will be ready in October or November.

The Yampa company, operating at Bingham, is making a far better showing under its new management. Mr. Moodie, general manager, has been developing more ore, and it is stated he has succeeded in mining and treating it at a good profit. The company is now shipping about 600 tons of copper ore daily to the Garfield smelter, and it is developing some lead ore also. Experiments on concentrating the low-grade copper ore will be made at the Winnemucca mill in Bingham. The Utah-Apex at Bingham, after having closed down its mill for nearly seven months during a period of active mine development, has again started up its concentrator. During that period the management has opened up two good orebodies, from which 150 tons per day of shipping ore is being sent out, while ore of milling grade is being developed. Within a short time the mill will be treating about 175 tons per day, it is expected. While little progress is being reported on the new financing of Ohio Copper, the operating department is pushing ahead rapidly. Some 40 of the 60 Deister slime tables recently purchased have been installed, the regular concentrating tables being taken from the slime plant and transferred to the main mill. The entire equipment is reported to be doing excellent work. The tonnage has been increased from 1500 to 1600 tons per day to 1700 tons average, while one day's run was 2100 tons, and it is said the saving is high. Despite an active opposition campaign, the old management of the Bingham Copper Co. was well supported at the annual meeting. The directors elected were: President, Carl Brandt; secretary, W. T. Wheden; treasurer, George E. Davis; R. J. Evans and W. D. Bohm. The method of financing the requirements of the company was left to the board. In a statement issued shortly after the meeting, the board stated its expectation of resuming active work at the property within sixty days. Two additional sections of the Arthur concentrator of the Utah Copper have been overhauled and remodeled, making a total of five sections in operation with the new Janney classifiers and Garfield roughing tables. When the work is completed the two mills will be ready to handle regularly 20,000 tons of ore per day.

There is a great increase in activity in the Park City district. At the Daly-Judge the connection made with the Ontario drainage adit on the 1900-ft. level is important. The water is being easily handled by the adit, and the company is at last in a position to mine the lower levels from which it has hitherto been kept. Known ore-shoots will now be opened up at depth, and vigorous exploration work will be continued. The company is installing Richards-Janney classifiers in the mill and is making other preparations to increase both efficiency and capacity. The Daly West has added two more tables to its mill, and the management reports favorable developments in several parts of the mine. The Silver King Consolidated has opened large quantities of high-grade ore in the Ida May and Spitfire raises. Following the recent judgment in favor of this company against the Silver King Coalition for $737,007, these developments have given a great impetus to the company. A long term favorable smelting contract is reported by the management. The old Ontario, pioneer in the camp, is taking on new activity. The shipments of ore from Park City for May amounted to 9823 tons.

TORONTO, CANADA

New Discoveries. Development in Outlying Areas. Underground Work at Rea and East Dome. Hollinger Mill. Ontario Mineral Production. Quarterly Dividends.

Further discoveries have lately considerably widened the mining area of the Porcupine district. The latest rush, which has taken away a number of prospectors from Porcupine, has been to Bristol township, about ten miles southwest of the Hollinger, where considerable excitement has been aroused by a find on a claim staked by John Bridge, of Haileybury. It consists of a 200-ft. dike, carrying quartz with free gold. The surrounding country is low and swampy, without any possibility of finding outcroppings, but a large area has been staked on the chance of future discoveries. The mineral associations are slightly different from those of Tisdale, the quartz and gold being accompanied by a quartz porphyry with a contact of granite-like rock in some localities. New finds in other outlying districts are being frequently reported, and prospectors are overrunning the country as far as the Sudbury district.

PUTTING IN PRECIPITATION TANK FORMS, DOME MILL.

In Keefer township, in the Cripple Creek district, H. M. Welch, one of the pioneer miners of Porcupine, is working four claims, on which he has a mineralized dike 150 ft. wide with a dome of blue quartz. In Ogden township, adjoining the Cripple Creek area, A. F. Worthington, of Toronto, is developing four claims, which have well defined quartz veins with good quantities of free gold. A shaft is being put down. One or more flotations of companies that operate in this section are likely to be made shortly. The Porcupine Gold Mines, generally known as the Vipond, is producing gold with a little one-stamp Nissen mill at the rate of about $1000 per month. A 10-stamp mill has been ordered with a capacity of 75 tons per day, there being enough ore available to furnish a supply for several years. A drift 420 ft. long has been opened up on the 100-ft. level, the high-grade streak of the vein being about 2 ft. wide. The Pearl Lake has ordered two prospecting stamps and a 20-drill compressor and is arranging to secure electric power from Sandy Falls on the Mattagami river. Shafts on No. 2 and B veins are down 55 ft., and cross-cutting on the first level has been started. At the Rea underground work is being carried on at the 200-ft. level, adits being run east and west, the vein showing up as well as on the

1910 the production was 9,911,608 lb. The company started the year with a production in January of 1,738,429 lb., and each succeeding month has shown an increase. This year's production is expected to be considerably in excess of that of 1910.

That the Esperanza, Ltd., the English company controlling the Esperanza gold mine in the El Oro district of the State of Mexico, is looking for another property is disclosed by the report of the company's consulting engineer. He states that during the past year no less than 29 properties were investigated, but none was considered sufficiently promising to be taken over. While it is denied that the end of the Esperanza is in sight, it is stated that the company is anxious to secure a mine that will be a guarantee of many more years of successful operation. At the end of 1910 there was an increase of 140,000 tons in the Esperanza ore reserve, the estimated total being 367,000 tons. Since organization, 7½ years ago, Esperanza has paid in dividends £2,229,000, equal to 490 per cent.

As a result of depredations committed by armed men, calling themselves revolutionists, at Salinas, State of San Luis Potosi, the power plant there was put out of commission, depriving the Salinas of Mexico, Ltd., and the Benito Juarez Mines Co. of power and forcing a suspension of work. The Salinas of Mexico is an English company controlling the principal salt enterprises of Mexico, and carrying on extensive operations at Salinas. The Benito Juarez company is a Los Angeles concern, operating several mines and a reduction plant. The mine workings have been flooded since the cutting off of power, and considerable damage has resulted.

SILVERTON, COLORADO

EXAMINATIONS OF PEERLESS SAN JUAN, KITTIMAC, AND TOM MOORE.—VERMILLION RESUMES SHIPMENTS.—GOLD KING REDUCES FORCE.—IOWA MILL TEMPORARILY CLOSED.—SILVER LEDGE EXAMINED.—PRIDE OF WEST SHIPPING.—CONGRESS SALE.

Little new capital has been invested in this district this year, but several important deals are pending. The Peerless San Juan is being examined in the interest of an Eastern leasing company, and the Kittimac and Tom Moore have been examined by an agent of the A. S. & R. Co. The results of these examinations have not been made public. The Silverton railroad was opened to Animas Forks early in June, and the Vermillion mine resumed shipments of concentrate June 15. The mill has been running six weeks and the company has nearly 500 tons of concentrate stored in the bins. New finds in other outlying districts are being frequently reported, and prospectors are overrunning the country as far as the Sudbury district.

PUTTING IN PRECIPITATION TANK FORMS, DOME MILL.

In Keefer township, in the Cripple Creek district, H. M. Welch, one of the pioneer miners of Porcupine, is working four claims, on which he has a mineralized dike 150 ft. wide with a dome of blue quartz. In Ogden township, adjoining the Cripple Creek area, A. F. Worthington, of Toronto, is developing four claims, which have well defined quartz veins with good quantities of free gold. A shaft is being put down. One or more flotations of companies that operate in this section are likely to be made shortly. The Porcupine Gold Mines, generally known as the Vipond, is producing gold with a little one-stamp Nissen mill at the rate of about $1000 per month. A 10-stamp mill has been ordered with a capacity of 75 tons per day, there being enough ore available to furnish a supply for several years. A drift 420 ft. long has been opened up on the 100-ft. level, the high-grade streak of the vein being about 2 ft. wide. The Pearl Lake has ordered two prospecting stamps and a 20-drill compressor and is arranging to secure electric power from Sandy Falls on the Mattagami river. Shafts on No. 2 and B veins are down 55 ft., and cross-cutting on the first level has been started. At the Rea underground work is being carried on at the 200-ft. level, adits being run east and west, the vein showing up as well as on the surface. The shaft will be sunk 100 ft. farther. A second shaft is down 60 ft. Surface prospecting at the Preston East Dome has disclosed 15 new quartz deposits. Diamond-drilling to a depth of 400 ft. has been undertaken with good results. In sinking on the properties of the American Gold Fields Co., adjoining the West Dome, ore running high in the sulphides was struck at 8 ft. The four claims of the Success Gold Mines in Tisdale township have been bought by W. Laing Malcolmson, of London, for about $600,000. Development will be pushed under the management of Ralph A. Meyer. The Hollinger will erect 60 stamps instead of 30 as originally intended, and the cyanide process will be adopted. Another company to supply electric power to the Porcupine camp is being formed. Hydraulic power will be obtained from High Falls, 14 ft. high, on the Frederickhouse river, a distance of 26 miles from Porcupine. The Scottish Ontario recently made a rich find of free gold at 18-ft. depth on No. 1 vein.

A statement issued by the Ontario Bureau of Mines gives the total value of the output of the metalliferous mines of Ontario for the first three months of 1911 as $6,808,769. The leading place is occupied by silver, the production of which was 7,530,487 oz., valued at $3,708,544, being an increase in value of $667,386 over the corresponding months of last year. Nickel showed a decrease of $246,032. The gold output for the three months was only 1813 oz., valued at $33,990. The Nipissing has declared its usual dividend of 5% with an extra 2½%. The La Rose still adheres to its conservative policy and will not raise its dividend over the regular 2%, although it announces a surplus of over $1,250,000. The Trethewey, which pays dividends intermittently, has declared a dividend of 10%. The smelter of the Canada Refining & Smelting Works at Orillia, Ontario, is now in successful operation treating Cobalt ore, and the erection of additional buildings which will double its capacity has begun.

NEW YORK

Peculiar Features of the Copper Market.—Inspiration Merger.—Annual Report of New Keystone.—Ray Central.—Low Working Costs.—Sale of Gold Roads.—Sale of Summit Mine.—News from Porcupine. Market Prices.

There has been a strong attempt to renew public interest in copper, and the improved demand has been made much of from every possible point of view. Apparently the main object to be gained at this juncture is an upward movement in copper shares, headed by Amalgamated. It is an anomalous situation, that in a period of general appreciation in prices, a staple in which production and consumption are running at record figures remains at or below the average price for the past ten years. In a way, the progress made in methods of treatment and in the handling of ore has reacted to the disadvantage of the copper producers. The present controlling factors in copper production have been built up at great expense, and can only operate on an immense scale. Already it is plain that the present fractional advance in price will stimulate production, and while improved figures will appear in the Producers' Association figures for June, it is safe to say that later months will show accumulated stocks again on the increase. Conditions must inevitably emphasize the necessity for adjustment between production and consumption. The legal obstacles in the way of a copper merger seem at present to be insurmountable, so much so that for the time there is no discussion of plans or possibilities to be heard.

The Inspiration-Miami consolidation appears to be definitely sidetracked for the time being. It is stated that the Lewisohns, on behalf of the Miami, suggested a joint ownership of power plant and concentrator. The Gunn-Thompson interests responded with a counter proposition of consolidation, but while numerous conferences were held, it was impossible to agree on a basis satisfactory to all. The Inspiration is to erect a 5000-ton mill immediately, and W. H. Aldridge, manager, and Henry Krumb, consulting engineer, for the company are now on the ground for the purpose of starting the work. The New Keystone Copper Co., which, like the Miami, is a subsidiary of the General Development Co., has completed its report for the year ended June 1, showing some 2,000,000 tons of developed ore averaging 2.25% copper. Discoveries made by the Live Oak, adjoining the New Keystone on the west are considered very important by the latter, and some further drill work is to be done in the belief that new orebodies will be found in the same formation developed by the Live Oak. A computation of the developed ore reserve of the Ray Central is to be given out within a short time. During the period covered by the option held by the General Development Co. on Ray Central, the latter had a large public. Interest in the issue has declined ever since J. Parke Channing made public his determination to reject the property. It seems the last word never will be said on lowered copper costs. Nevada Consolidated is stated to have made its May output under 6c. per pound, and is working for still lower costs by constructing new converters, the largest in the world, and rebuilding reverberatory furnaces for the use of fuel oil. The various developments at Butte point to an increased production. There has been a steady advance in North Butte predicated upon betterment in ore reserve. The East Butte is building a third furnace at the Pittsmont smelter, and this mine will be producing 1,500,000 lb. monthly as soon as the price will justify it. The Tuolumne is installing a Nordberg hoist, and will be ready to make a greatly enlarged output within a short time. The issue is one of the strongest among the active copper shares traded in in New York.

It is definitely announced that the United States Smelting, Refining & Mining Co. has completed its negotiations for the purchase of the Gold Roads property near Kingman, Arizona. The agreed purchase price is $1,400,000. The property is said to have been purchased on the strength of ore developed approximately equivalent to the figure asked. There is a little mystery concerning the active canvass being made for proxies by some of the heavier holders in the Montgomery-Shoshone Consolidated Mining Co. The concern, once the pride of Charles M. Schwab, is to be wound up, the mill sold, and nothing remains to be done except to get the requisite authority from the stockholders. Inasmuch as the company's last statement showed some $225,000 due Mr. Schwab for money loaned, and as the mill and other equipment to be sold can hardly bring half that sum, it is a little curious that the requests for proxies should be so numerous and urged so strongly. The directors of the Tonopah-Belmont held a special meeting at Philadelphia this week and voted to erect a new slime mill of 500 tons daily capacity.

It is said that D. Lorne McGibbon and Frank C. Armstrong have purchased the Summit Gold mine on Sheep creek, near Nelson, in British Columbia. The interest in Porcupine is reawakening in the East. The opening of the railroad, a sensational strike on the Porcupine Gold Reef, in what is known as the Bannerman district; another on the North Dome, the latter being owned almost wholly on this side of the line, the property having been financed by Catlin & Powell in New York and London, where the issue is active on 'change. The class of new offerings is worthy of comment. The Daly-Taylor, the Ontario Porcupine Goldfields Development Co., are examples of the better class. The Development company is the Bewick-Moreing organization, to be under the direction of Gerrard Lovell, recently chief engineer of the Great Burmah Silver Mines in India and formerly of the Great Fingall Gold Mines in Australia. The Timmins-McMartin interests, which dominate the Hollinger, are on the advisory board of the Development company. The principal adverse comment is anent the lack of cohesion in the market for Porcupine shares. Hollinger has advanced bravely from around $6 to $16, but it has advanced alone, the tendency in other issues being, on the whole, toward lower levels. The fear is expressed that a market fiasco in Hollinger might have the same effect as did the unfortunate episode in Nipissing in the early days of Cobalt.

General Mining News

ALASKA

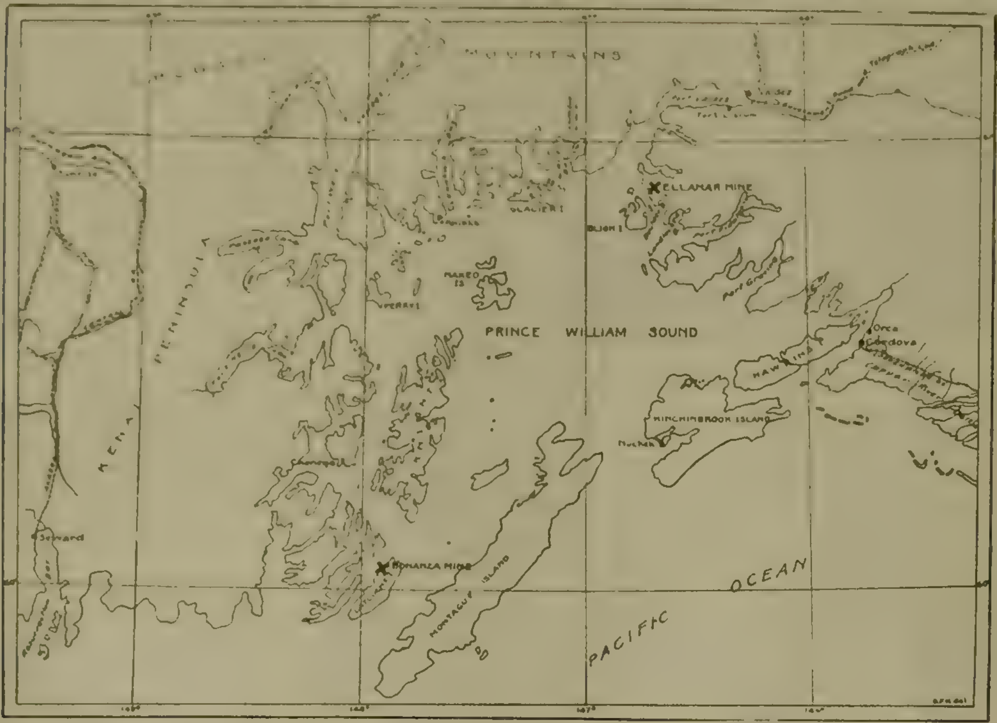
Juneau District

The report of the Alaska Mexican Gold M. Co., Douglas island, for the month ended May 15, 1911, shows that the 120-stamp mill was operated practically full time, that 15,936 tons of ore was crushed, and 128 tons of concentrate was saved. The estimated gross value of free gold recovered was $22,251; base bullion, $1324; concentrate, $24,404; total, $47,980; less $4383 for 2124 tons of ore from United 700 mine, $43,597. Estimated total realizable value of product, $43,161. Operating expenses, $28,275; net operating profit, $14,888. Construction expenses, $2601. Yield of ore milled, $2.77 per ton; stock of ore broken, 4713 tons; development, 108 feet.

Prince William Sound

The Vancouver Valdez M. Co., M. S. Kain manager, is developing its mining claims on Shoup bay, near Valdez. An adit-level is being driven on the vein. The ore found in the adit and in the vein cropping is of such grade as to justify confidence in further development. There is reported at Valdez a growing tendency to encourage the leasing system as a means of developing the mining resources of that region. Among those who recently located mineral claims between tidewater and Shoup glacier are J. E. Haggerty, E. F. German, L. Graham, D. Sheehan, R. A. Clousterman, Harold Graham, C. H. Hill, M. L. and J. B. McAllister, J. O'Brien, H. L. Jaynes, and Joseph Child.

The 40 claimants who filed on coal lands known as the Stracey group, situated in the same locality as the Cunningham claims, have been cited by the Juneau land office officials to show cause why their claims should not be recommended to the Commissioner of the General Land Office for cancellation. A special agent of that department has charged that the claims were not made in good faith, but that each claim had been filed upon under an agreement with the Alaska Development Co. and the Pacific Coal & Oil Co. It is said that the claimants are Seattle men, and that A. H. Stracey of Vancouver, B. C., was concerned in the alleged effort to secure 6400 acres of coal land for these companies. The Secretary of the Interior, on June 26, disallowed the 33 coal land claims of the Cunningham group, about which there has been such a protracted controversy, on the ground that the claimants were under agreement to turn the property over to a syndicate as soon as title was secured, which was held to be in direct violation of the law. Patents will not be issued, and the claims are ordered canceled.



PRINCE WILLIAM SOUND, ALASKA.

Seward Peninsula

The spring clean-up of winter dumps on the Nome tundra is estimated at $400,000.

The Tanana

George Lamontagne, who with three partners composed the Union Mining Co., which operated as a lessee on No. 17 Goldstream, near Fairbanks, during the seasons of 1908, 1909, and 1910, has sold out his interests there and has purchased a mining property on Kenai peninsula, which he is developing. No. 17 Goldstream, which belongs to L. L. James & Co. of San Francisco, is said to have yielded about $1,000,000 in the three seasons named.

ARIZONA

Cochise County

A custom concentrator is to be built at Paradise by Ray people, represented by R. H. Hickey. The proposed mill is expected to be operated on ores produced in the Chiricahua mountains, where there are a number of mines which are small producers. Paradise, the centre of the district, is 20 to 30 miles from the nearest railroad station.

The labor liens, amounting to $29,000, filed against the Tombstone Con. Mines Co., since its mines closed down last winter, are expected to be paid off in July, and that the company may be able to resume operations in August. The 100 miners who were working for the company at the time work was suspended have since then been working in the mines as lessees. The leased ground is above water-level where there are high-grade streaks of ore. By this arrangement the Tombstone camp has been kept fairly active.

Greenlee County

The *Copper Era*, published at Clifton, announces on the authority of a director of the Arizona Copper Co., at Edinburgh, Scotland, that this company has decided to build new smelting works to supplant the old works which have been in use over a quarter of a century, and that in the designing and construction of the proposed plant L. D. Ricketts has been engaged as consulting engineer. The site selected for the new plant is on the San Francisco river, 3 miles downstream from Clifton.

The Frisco Placer M. Co., made up of several people at Morenci, has acquired the Lennox placer holdings on the Frisco river, below Clifton, upon which a plant has been erected, consisting of trommels, sluice-boxes, and Pierce amalgamators, by which it is expected to wash and sluice about 4000 yd. of gravel per day. J. M. Erickson is in charge. It is claimed the ground has been proved rich in gold by test runs.

Mohave County

The Tennessee mine has two veins, one of which is being opened by a cross-cut from the 700-ft. station. By this means a level will be established on the Tennessee vein 100 ft. below the old workings. The other vein is being opened by driving a cross-cut from the 500-ft. station of the same shaft. The mine belongs to the Needles Mining & Smelting Co., and is at Chloride. The Gold Bug M. Co., for which O. B. Amsden is manager, has developed enough ore in its property in the River range, west of Whitehills, to warrant the building of a mill. It is stated that a plant will be built as soon as a water-supply is assured. The ore is gold bearing and the mine is being developed from a 500-ft. shaft. The property is 30 miles from Chloride.

The Frisco Mines & Power Co., operating at Union pass, is milling ore that assays $12 per ton, and it is claimed an extraction of 90% is being made. The principal metal in the ore is gold, and this is extracted by cyanidation, preceded by pulverization in a Hardinge conical mill and a tube-mill. This company has purchased the old Burns ranch on account of its water-supply, which is to be piped to the mine, situated 25 miles from Kingman. H. W. Squires is the company's manager.

Yuma County

Doten brothers have given a lease and bond on their claims in Castle Dome district, situated about 40 miles east of Yuma. The ores of that region contain silver and lead, the camp lies several miles north of the Gila river, and the prospective purchasers are Los Angeles people. A carload of ore mined on the Singleton claims, near Kofa, was hauled to the railroad and shipped to market. Charles Sam has shipped two cars of ore from his Ironwood claims, in the same locality. This ore assays $50 to $100 per ton.

CALIFORNIA

Amador County

The Ione mine, situated on the Campo Seco zone, has been developed by a 300-ft. shaft, and is equipped with a steam hoist and a small concentrating-mill. The ore content is principally copper, with which is some gold and silver. The shipments of ore lately have amounted to about 1000 tons. D. T. McLennan is in charge of the property.

(Special Correspondence.)—The South Eureka shaft has reached an incline depth of 2800 ft., with drifts from the 1600 and 2750-ft. levels connecting with the Central Eureka shaft. The 80-stamp mill is running on ore from the two west veins, the principal orebodies of the mine. These veins occur in slate, about 800 ft. apart, and in places attain a width of 40 ft. The average width ranges from 25 to 35 ft. The ore assays approximately $6.50 per ton. The veins dip toward each other and may be found to meet below the 3000-ft. level. The ore-shoots have been explored for a distance of about 500 ft. They show a width of fully 40 ft. in some places. On the 2000-ft. level a 10-in. vein carries quartz assaying $1500 per ton. This has been prospected for 135 ft. On the same level an 8-ft. shoot has been opened about 100 ft. This orebody contains good ore and is expected to extend to the hanging wall. It is estimated that 900,000 to 1,000,000 tons of ore is developed, or sufficient to keep the mill in operation for over seven years. The mill has sixteen 5-stamp batteries of 950-lb. stamps, operated by four 50-hp. Westinghouse motors, and crushes 400 tons per day. The recovery is by plate amalgamation. The pulp passes from the plates to 6 6-ft. Frue vanners. At present this completes the treatment, but arrangements are being made to provide a canvas-plant to handle the tailing. The South Eureka ores carry a high percentage of sulphide, which is shipped to the Selby smelter at Vallejo Junction. Mining and milling costs average $2.63 per ton, and 250 men are employed. The company is disbursing regular monthly dividends of 7c. per share, aggregating $21,000. The directors are seriously contemplating the sinking of a new shaft and the construction of another mill, as under present circumstances one shaft and the mill now in use are inadequate to handle the tonnage of ore to best advantage. The proposed shaft, if sunk, will be west of the present one, which will bring the main workings closer to the orebodies. V. H. Schmal is superintendent.

The orebody on the 1950-ft. level of the Bunker Hill is proving one of the most remarkable ever opened on the Mother Lode. In places it is 80 ft. wide, and the ore is of sufficient value to be milled direct. Practically all the ore now being treated comes from this level, although of lower grade than in the upper workings. The 40-stamp mill is producing about $30,000 per month. The company has declared dividend No. 60 of 5c. per share. Operations were resumed at the Amador Queen on June 19. The shaft will be cleaned out and explorations conducted in hopes of intersecting the old shoot. The South Jackson Gold Mining Co. has been formed to develop a group of claims lying southwesterly of the Zeila mine. The directors are W. P. Miller, San Francisco; John McSorley, Mokelumne Hill; Adam Huberty, C. F. Vicini, and F. W. Ruhser, Jackson. The owners of the Jackson copper mine, 12 miles southeast of Jackson, report the uncovering of a new orebody. The vein is said to carry copper ore of good grade. The property was recently equipped with a gas-engine, air-compressor, and machine drills. The vein recently intersected at the Lincoln Con. is reported to be looking well. Driving from the 1200-ft. level is being pushed to intersect the orebody at depth.

Jackson, June 24.

Butte County

The placer property of the Mineral Slide Gold M. Co. is three miles from Magalia. Part of the work in progress consists in extending what is called bedrock tunnel No. 10 to the opposite border of the property. It is now in several hundred feet, and is expected to tap the channel of gold-bearing gravel at its lowest stratum. It is being driven on a grade that gives it a rise toward the heading of 10 in. to every 16 ft. The plan is to pipe water to the breast of the drifts and sluice the gravel out through the tunnel.

(Special Correspondence.)—The Indiana dredge is being worked on the gravel of the Feather river below the bridge. When the two dredges of this company were overturned during the high water, amalgam valued at $6000 was lost, and it is expected that the Indiana will recover part of this during the next month. R. E. Lyons, examining engineer for the Yukon Gold Co., is in Oroville en route to Alaska and Dawson to make tests on the platinum and other rare metals of placer deposits, and to study methods of saving same for his company.

Oroville, June 24.

Calaveras County

The Dolling Gold M. Co. is operating a 40-stamp mill at Angels Camp, treating about 150 tons of ore per day. This ore runs $2.50 to $3 per ton in gold. The mill is operated by electric power, and the ore is hauled from the mine in cars over a surface tramway. The costs of mining and milling are close to $1.25 per ton.

Inyo County

The Skidoo Mines Co., operating at Skidoo, during the month of May milled 1404 tons of ore, recovered bullion valued at $17,861, and cyanide precipitate worth $[illegible], received $1272 as royalties and charges for custom milling, making a total of $[illegible]. The operating costs amounted to $7820, the expenditure on development work was $1148, making a total of $8968, leaving net profits for the month of $15,014.

SIERRA COUNTY

The Red Star mine, near Alleghany, was under bond for three years to Denver people who were represented by L. P. Woodbury. During the term of this bond about $100,000 was expended on equipment, buildings, and in development work. The time expired, those who held the bond decided not to take it up, and the property reverted to H. L. Johnson, who put a force of men to work sinking where previous development had been in progress. The result was the discovery of high-grade ore, some of the best samples of which were estimated to be worth $20 to $30 per pound.

SISKIYOU COUNTY

(Special Correspondence.)—The Siskiyou Coal Co. reports finding of a large seam of lignite coal in Shasta valley, near Agen. The coal is said to be of good quality and the company is arranging for greater developments. Prospecting has been going on for several weeks, the property having previously yielded several hundred tons of fair-grade coal.

W. W. Turney, representing New York investors, has purchased 1000 acres of placer ground along the Klamath river, near Happy Camp. The company, known as the Siskiyou Mining Co., has also acquired water rights to 5000 in. of water from Thompson creek. The operations will be with hydraulic giants. The Riverhead Mining Co. is working a group of gravel claims on the Klamath river by means of a steam-shovel. The gravel is dumped by cars into an elevated flume which transports it by gravity to the sluices. It is said the operations are profitable. A. B. Aiken is superintendent. The Bullion Mountain M. Co. is developing a group of claims on Hungry creek, about eight miles from Hilt. The group includes the Last Chance, Tomahawk, E. A. C., Missing Link, and Rose Lee claims. The E. A. C. is developed by two adits, one 320 ft., the other 150 ft. long, with a 40-ft. raise from the latter. At the Last Chance the tunnel is in 450 ft., while 200 ft. has been driven on the Tomahawk. The ore in the E. A. C. vein is said to run about $65 per ton. A shoot of ore, 20 to 24 in. wide, has been intersected in the Cub Bear mine, near Snowden. The ore is said to contain tellurium, and much free gold. The property is controlled by the Siskiyou Syndicate. W. E. Everson is general superintendent.

Yreka, June 24.

COLORADO

LAKE COUNTY (LEADVILLE)

The *Carbonate Chronicle* of Leadville reports that many of the old shafts on Fryer hill have been retimbered and made active by lessees. Nearly all these properties, on which work has been commenced within the last six months, have ore exposed. Active shafts include the Hayden, Chrysolite, Little Chief, Virginius, Amie, Sliver, Matchless, Climax, Dunkin, and Discovery.

The opening of fissure veins in granite, in Leadville district, is regarded as most important. One of the first of these discoveries was that of the Cleveland fissure, on South Evans gulch. This has been opened by drifts on different levels from the Cleveland and Valley shafts. Gold, silver, lead, and copper ore has been found in the vein on both properties, and a considerable tonnage has been shipped from the Cleveland. The continuity of this fissure is being demonstrated on the Cleveland, Valley, and Silver Spoon, and the development in progress on the Great Western and Great Eastern groups is expected to show its extension to the northeast. The last two groups named had been idle since 1880, when early this year they were leased to George W. Cook and W. G. Boyle. George Argall, now manager for the Iron-Silver M. Co., has found ore at the depth of 1210 ft. in the Tucson mine of that company, the ore containing gold, silver, copper, and lead.

SAN MIGUEL COUNTY

The Emma mine, situated in Ice Lake basin, near Telluride, belongs to J. A. McCrimmon, and is being operated by John Mativi and associates, as lessees. The ore being mined assays 60% lead and about 45 oz. silver per ton. It is carried by pack animals to the foot of the mountain, then hauled in wagons to the railroad. The Black Bear mill is being operated at part capacity on good ore. The product consists partly of amalgam and partly of concentrate.

TELLER COUNTY (CRIPPLE CREEK)

Dahlgren, Leddy, and Ball, working leased ground on the Last Dollar, Bull hill, have opened a 4-ft. vein of ore at the depth of 112 ft., the ore assaying about $18 per ton. They are working through No. 1 shaft, and have done considerable development. O. D. Fogleman and associates, lessees of the W. H. P. mine, Ironclad hill, are keeping up shipments of ore from the lower workings, and at the 300-ft. level the ore in a 3-ft. vein averaged $45 per ton. Within this vein was a 3-in. streak of stuff that ran 10 oz. gold per ton. Fogleman and Vaughn, having a lease on a block of Ajax ground, Battle mountain, sent out a car of ore that sampled close to $50 per ton. One vein on which they are mining has a width of 3 to 5 ft., the ore in which averages about $40 per ton. The Ajax mill is expected to be in operation this month. The Strong mine, at Victor, is producing about 40 cars of ore per month, most of which is high grade. A recent shipment of two cars of ore, taken from the 1000-ft. level, sampled $100 per ton. The Anaconda mill has been supplied with some new equipment, making it more modern, and is now in operation on low-grade ore.

ISABELLA MINE, BULL HILL, CRIPPLE CREEK.

The Western Reduction Co. has a cyanide plant of 300 tons daily capacity ready to operate on Isabella dump material, which is estimated to contain $1 to $1.25 in gold and silver. It is figured that this can be treated at a cost of 30c. per ton. The Cripple Creek Mining & Metallurgical Society has been organized, with Philip Argall, Jr., as president, and Fred Jones as secretary. The members of the society meet once a month, when a prepared paper is read, and this is followed by discussion.

Ritchie and Rose, who have a lease on the Pinto mine of the Free Coinage Gold M. Co., Bull hill, are mining 15 to 20 tons of ore per day from an orebody that measures 8 ft. between walls. This ore samples about $30 per ton. The first car of ore from this shoot was recently shipped. Between May 1 and June 15 there were shipped 33 cars of ore from the Mabel M. and Husted shafts of the Gold Dollar group, on Beacon hill, which averaged about $25 per ton. Ore shipments at the rate of a car per day are being made by Olsen and Van Tilborg, lessees at the 400-ft. level of the Trilby main shaft. Jones & Nicholson have the contract to drive a 600-ft. cross-cut on the 600-ft. level at the Blanchard shaft of the Hiawatha mine, Beacon hill. The Cavanaugh M. & M. Co. has a long-time lease on the dumps of the Jo Dandy mine, and is building a cyanide plant in which to treat this dump material and some of the low-grade ore direct from the mine. The mill is expected to be ready for work this month. The mill of the Blue Flag Gold M. & M. Co., Raven hill, is to be operated again. It has the capacity of 100 tons of ore per day. The Montrose mine, Ironclad hill, has been leased for three years to the Pride of Cripple Creek M. & D. Co. of Colorado Springs. The leased ground is to be developed and worked through the 600-ft. shaft of the Pride of Cripple Creek mine, which is also being operated by this company.

IDAHO

BONNER COUNTY

The Pondera Group M. Co. has performed 4000 ft. of development work on its claims near Sand Point, has opened an 8-ft. vein of silver, copper, and gold ore, running over $100 per ton, and announces that a carload of sorted ore is to be shipped to a smelter.

LEMHI COUNTY

The Leesburg Gold Dust M. Co., controlled by Salt Lake City men, has four lode claims and a placer claim at Leesburg, which is 14 miles from Salmon, the nearest railroad town. A contact vein, said to be 80 ft. wide, has been opened and developed to some extent by means of a 387-ft. cross-cut. The ore has sampled $2.80 to $7.40 per ton in gold, and it contains some silver. A 10-stamp mill was built some time ago, and now equipment for cyaniding is being put in place. The intention is to treat a lot of tailing that has accumulated at the mill.

SHOSHONE COUNTY

The Stewart Mining Co., owner of the Stewart mine, in the vicinity of Kellogg, is sending about 500 tons of ore per day to its leased mill at Wallace to be concentrated, and is marketing at the smelters between 450 and 500 tons of high-grade ore per month. It is asserted that the company is out of debt and that its ore reserves are being increased.

The Coeur d'Alene Development Co., owner of the Silver King mine, on Government gulch, near Kellogg, is being reopened and further developed under direction of Robert Sterling. The mine is to be worked through an adit, now in 450 ft., and which is being extended. This property was formerly a producer of high-grade lead-silver ore, but it had been idle eight years prior to the time the present operations were commenced.

The Marsh M. Co., which is making a success of its operations on the Marsh claims at Burke, is concentrating its ore at a leased mill on Nine Mile, and is reported to be shipping 65 tons of concentrate per day. Within six weeks the gross returns for concentrate marketed was $24,500, the net profit being $9500. The ore being milled is taken mostly from the stopes above No. 2 adit.

Recent improvements made at the Gold Hunter mill, at Mullan, raised the capacity to over 400 tons of ore per day. The mill is about ready to be operated again. The Snowstorm M. Co. has opened a shoot of ore by driving from its No. 4 cross-cut, by which the ore zone was tapped at a depth of 1900 feet.

MICHIGAN

HOUGHTON COUNTY

The Hancock has been shipping six carloads of ore per day, from which was extracted 25 lb. of copper per ton. The Winona Copper Co. is milling 360 tons of ore per day, although its new mill, built at a cost of $300,000, has a capacity of 1500 tons. The tonnage sent to the mill is being gradually increased, however. The Mass Copper M. Co. has acquired the Evergreen group, which enlarges its holdings to 5000 acres. It is mining and milling 280 tons of ore per day that yields about 20 lb. copper per ton. The company's B shaft, which has a depth of 1800 ft., is to become the main working shaft.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The Jumbo Extension Co. is driving south on the Polverde claim, adjoining the Clermont and Laguna claims of the Consolidated, on the 1030-ft. level from the Goldfield Annex shaft. The Annex lessees have shipped some good ore from the 800-ft. level, have exposed ore on the 760 and 850-ft. levels, and have cut a station at 600 ft., near which point the shaft entered the vein. On July 15 the Jumbo Extension company will pay its initial dividend of 10c. per share. This was made possible by the recent sale to the Consolidated of a one-half interest in the Vinegorone claim. After the dividend is paid the Jumbo Extension company will have a cash balance of more than $100,000 in its treasury. Later the work of development will be extended to the northern part of the Polverde claim on the 1030-ft. level. This shaft is 1070-ft. deep, has two compartments and manway, and is well equipped for deep mining.

NYE COUNTY

The Tonopah-Belmont Development Co. has decided to proceed with the construction of a reduction plant of 450 tons daily capacity. The millsite selected is a short distance south of the Belmont shaft. The mine is producing about 1700 tons of ore per week, that of lower grade being treated at the company's old mill at Millers, while the high-grade ore is shipped to smelters. The deepest workings from which ore is now being extracted in the Belmont are on a drift from a winze which was sunk 35 ft. below the 1166-ft. level.

Work has been commenced on the mill at the MacNamara mine. The plant is to contain two 5-stamp batteries of 1250-lb. stamps, working in mortars having 4-ft. bases, a height of 15 in. between mortar block and the dies; a Dorr classifier, a tube-mill, a 26 by 12-ft. Dorr thickener, two Trent agitating tanks, a 40-leaf vacuum filter, and zinc-boxes for precipitating. The machinery is to be run by electric power, and the plant is to have the capacity of 70 tons per day. The company is controlled by San Francisco men, Herbert Haas being manager.

STOREY COUNTY (VIRGINIA CITY)

The output of the Mexican and Union mines for the week ended June 24 was $21,504; that of the Ophir was $5715. The tonnage and grade of Mexican ore is shown by the following: The 18 mine-cars extracted on the 2300-ft. level assayed an average of $62.83 per ton; ore from the 2400-ft. level consisted of 30 cars running $18.13, 17 cars assaying $11.23, and 6 cars at $15.70; that mined on the 2500-ft. level consisted of 39 cars averaging $77.73, 6 cars running $45.88, 169 cars assaying $87.92 per ton. The 166 mine-cars hoisted from the 2100-ft. level of the Ophir shaft averaged $88.10 per ton. The Mexican company, for the week, shipped three railroad cars of ore to the smelter. The shipment of Ophir ore to the Kinkead mill amounted to 148 tons. The Chollar company received $826 in royalities from Hahnewald brothers on ore they extracted during May, and the Potosi company received $1166 in royalties from the same source. During the week ended May 24 there was treated at the Yellow Jacket mill 1202 tons of ore from the Jacket dump.

NEW MEXICO

(Special Correspondence.)—Gold Dust Mines Co. has three shifts of miners at work on the lower tunnel, which will intersect the vein 450 ft. below the first tunnel. The Deadwood mill is now operating with 15 stamps. A large part of the ore treated is now coming from the third level, recently unwatered. The gravity water systems affords an ample supply all summer. The Ernestine Mining Co., on June 10, made a clean-up of 7350 Troy ounces of gold and silver; 5 tons of concentrate was shipped for the same period. The past week's tonnage of ore treated was 600, with 45 sacks of concentrate. The plant is again running at full capacity.

Socorro Mines Co. will probably order a De La Vergne high-compression oil engine, to supplant the wood-burning engines on Whitewater creek. The reduction plant continues its large shipments of bullion and concentrate. The Enterprise Mining Co. is making alterations in its mill, and some special machinery will soon be received.

Mogollon, June 24.

OKLAHOMA

The new Oklahoma School of Mines, at Wilburton, is to have an unusually complete ore-dressing laboratory. The contract recently awarded to the Allis-Chalmers Co. provides for a crushing plant having Blake, Dodge, and Gates crushers, a Bridgman automatic sampler, and a sample grinder. For fine crushing a tube-mill, steam drying pans, and ore bins are provided. There are three elevators and three sets of screens, also two sets of rolls with feeders. For concentration a 4-compartment and a 2-compartment jig are provided, also a Callow pulp-thickener, two small tables, and a Frue vanner, together with the necessary pumps. For stamping a battery of five 500-lb. stamps, together with the necessary ore bin, feeder, copper plates, amalgam trap, and pump are provided, also a 3½-ft. Huntington mill. Completely equipped cyanide and chlorination plants are also provided. For magnetic separation a Dings separator, with its accessory equipment will be used. The machinery will be motor-driven and the total cost of the laboratory will approximate $25,000.

OREGON

BAKER COUNTY

The Golconda mine, situated near Bourne, and under bond and lease to W. H. Turner of Spokane, and his associates, will soon be unwatered. On June 15 the water had been lowered to the 300-ft. level, and by now the 400-ft. level is probably free of water. The mine had been idle about seven years. Frank E. Pearce, operator of the Morning mine, in Greenhorn district, 20 miles from Sumpter, made a clean-up of 70 oz. gold, and he is just getting started.

JOSEPHINE COUNTY

A mining congress is to be held at Grants Pass on July 18, at which a good attendance of mining men from Oregon and adjoining States is expected. An exhibit of ores and mineral products of western Oregon is being prepared.

The Grey Eagle mine, in Gold Hill district, has been leased by the Oregon-Gold Hill M. Co. to the Grey Eagle M. Co., for which W. B. Stevens is manager, and J. R. Wolfe consulting engineer. The property is equipped with a new mill, an air-compressor, and drills. The plan of the lessee is to do 500 ft. of sinking from the 125-ft. station of the shaft.

James T. Logan and Schmitt brothers, who had a 30-day option on the Higgins property, in Cheteo district, declined to carry out the terms of the option, claiming the time had not been long enough to allow them to determine as to the probable merits of the ground. Higgins declined to extend the time. The price named in the option was $50,000.

TEXAS

EL PASO COUNTY

(Special Correspondence.)—The Hazel mine, situated 16 miles northwest of Van Horn, recently passed into the hands of George Culter, and he is preparing to unwater the old workings and resume operations. Pumping machinery has been provided. This mine has a record of having produced much rich ore, but it has been shut down for several years. The workings extend to a depth of more than 800 ft., and the task of unwatering them is a big one. The shaft and levels will be re-timbered. The old Sancho Panszo mine, in the Van Horn district, is to be reopened by J. C. Hay. This property was worked more than 20 years ago by Peter Nicol, L. H. Davis, and Joseph Beech. They found a pocket of ore averaging about $100 in silver and copper per ton. The Black Shaft mine in the same district has been leased and bonded by a syndicate of Minnesota men who are preparing to start development. The workings of this mine extend to a depth of 300 ft., and it is said to contain a body of copper and silver ore.

Van Horn, June 24.

UTAH

BEAVER COUNTY

A lot of 250 tons of zinc-iron ore has been shipped from the Horn Silver mine, at Frisco, to Midvale for treatment at the plant of the U. S. S. R. & M. Co., which is equipped with concentrators and the Huff electrostatic separators. If the results prove as satisfactory as anticipated, steady shipments probably will be made to that plant.

JUAB COUNTY

A body of ore, not previously found, is being developed on the 800-ft. level of the Mammoth mine, Tintic district. About four carloads of ore per week is being mined on this shoot and shipped to the smelters, the gross proceeds being close to $2000 per car. Work is being performed on the 1000-ft. level in an effort to open the same ore-shoot at that depth. This mine is in charge of Samuel McIntyre, one of the owners.

The exploration work being done in the Centennial Eureka mine, at Eureka, consists in driving from the 2200-ft. station for the orebodies which were worked on higher levels. The driving done thus far aggregates 1500 ft. This work is below water-level, and it is to be connected by a raise with similar drifts on the 2000-ft. level. The sinking, which has been in progress for some time at the Sioux mine, is finished, and driving for ore from the lowest station has been commenced. Ore shipments are being resumed at the Sioux.

The May shipments of ore from the Eagle and Blue Bell mine, at Eureka, amounted to 6 carloads, which sampled about $18 per ton in gold, silver, and lead. During June ore was mined on the seventh level which was higher in grade, and there was an increase of tonnage.

SALT LAKE COUNTY

The mill of the Ohio Copper Co., at Lark, is concentrating 1700 tons of ore per day, and is said to be making a higher saving than at any previous time. The Wilfley tables have been removed from the slime-plant to the main concentrating mill, and their place in the slime-plant has been given to 60 Deister slime-tables. The mining and milling operations of the company are in charge of Al Frank.

The ore found on the tenth level of the mine of the Utah Con. runs much higher in copper than that mined on the higher levels. The tonnage sent to the smelter has been increased since this orebody was developed.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The San Poil Consolidated Co. is driving northward on the vein in the North San Poil ground on the lower adit-level and continuing the raise. The machinery is working satisfactorily, and the ore shipments have been increased.

The Hope Consolidated Co. is shipping the second carload of ore from a newly developed vein, at a depth of 60 ft. below the adit-level. This is a lateral vein 7 to 10 ft. wide. The pay-streak is 4 ft. wide and at present follows the hanging wall. A cross-cut from 100 ft. below the adit-level is in 200 ft., with a similar distance ahead to the main vein. The ore shipped averages about $30 per ton.

A streak of $130 gold-bearing ore, about 12 in. wide, has been found in a new winze in the Morning Glory mine.

Republic, June 25.

SPOKANE COUNTY

C. E. Mitchell, a mining promoter of Spokane, was convicted of using the United States mails to defraud in connection with promotion schemes, and was sentenced to serve one year in the Federal prison, and pay the costs of the case.

MEXICO

CHIHUAHUA

(Special Correspondence.)—Conditions at Parral, so far as they concern mining operations, are normal and operations are active. The Veta Colorada Mining & Smelting Co., for which C. F. Spaulding is manager, shipped seven tons of silver bullion from Parral to Monterey on June 20. This was bullion that had accumulated during the insurrection period when the express companies declined to take the risk of shipping it. The company's property is at Villa Escobedo, fifteen to twenty miles from Parral.

Parral, June 22.

Company Reports

UTAH COPPER CO.

The report of the Utah Copper Co., operating the great **porphyry copper mines at Bingham, Utah, and controlling** the Nevada Consolidated, includes reports by the president, **C. M. MacNeill, the general manager, D. C. Jackling, and the certified public accountants, Edward P. Moxey & Co. Collectively they give an excellent insight into the opera**tions and present conditions of the property. Engineers will be mainly interested in Mr. Jackling's report, though the following summary from Mr. MacNeill's, gives the **briefest statement of conditions.**

The net profits for the year ended December 31, 1910, amounted to $5,401,775.23. Of this sum $3,890,912.41 was the profit resulting from the operation of the plants in Utah. After payment of dividends aggregating $4,648,675.50, together with interest on a few outstanding bonds—$187.50—or a total of $4,648,863, there remained a balance for the year of $752,912.23, which was passed to undivided profits. The total amount standing as credit to undivided profits on December 31 last amounted to $3,696,539.06, and is the amount over and above dividends and interest charges **which has been derived from operating profits and income. Undivided profits in no way has any bearing upon the** amount shown as surplus, of $6,083,980. This is the amount received in cash from the sale of stock in excess of the par value thereof. On December 31, 1909, the issued capital **stock was 734,375 shares. On December 31, 1910, the total** issued capital stock was 1,562,599 shares, an increase during the year of 828,224 shares. This increase is accounted for, being the acquisition of the Boston Consolidated Mining **Co.'s property, 310,000 shares; that of 1,000,152 shares of** stock of the Nevada Consolidated Copper Co., 444,512 shares; sales for cash at $50 per share, 73,437 shares; and conversion of bonds. The total authorized stock of the **company is 2,500,000 shares. There remains unissued, there**fore, 937,401 shares. But $2000 par value of the convertible bond issue now remains outstanding. Quarterly dividends were paid during the year at the rate of $3 per share per annum.

Because of the acquisition within the year of the Boston Con. holdings the ore reserve has been entirely re-calculated. **Mr. Jackling's statement, condensed below, is illustrated** by maps and sections not reproduced for lack of space.

The total area of mining claims owned is shown in the **following table:**

	Acres.
Original Utah Copper group	195
Original Boston Consolidated group	359
Shawmut Consolidated group	100
Outlying fractional claims	11.5
Total area of lode mining claims	665.5

The total acreage of land, other than lode claims, owned **by the company, is as follows:**

	Acres.
Lands in Bingham canyon	1586
Lands at and near Garfield	3377
Lands in Utah county	509
Total	5472

The underground development of the original Utah group during the year consisted of driving 1480 ft. of adits, which, added to the 179,861 ft. previously driven, makes a total of underground work on this portion of the property, at the end of the year, of 181,341 ft., or 34.34 miles. Previous to 1910, the underground work on the Boston Con. consisted of 109,876 ft. of adits, drifts, and raises, and **during the year an additional 45,567 ft. was driven, making** a total of 155,443 ft., or 29.44 miles. The total length of all underground work done on both groups, up to the end **of 1910, was therefore 63.78 miles. A considerable por**tion of this underground work has been destroyed by steam-shovel operations on the Utah group, and by underground mining on both groups, the total length so destroyed being 20.43 miles, leaving now accessible in both groups 43.35 miles of underground openings. Churn-drills were operated on both groups for a portion of the year. During the period sixteen drill-holes were driven, the total number of feet drilled being 6209. Previous to 1910 there had been drilled on the property seven diamond-drill holes, having a combined footage of 2609, and four churn-drill holes, aggregating 1197 ft., making a total of all drilling for development purposes on the property of 10,015 ft. The cost of underground development for the year amounted **to 7.02c. per ton on all ores mined and shipped to the mills.** This cost was charged against operations, and is included in the per ton mining costs hereafter stated. By the **acquisition of the Boston Con., and by further development** during the year, the total area of fully and partly developed **ground was increased to 166.15 acres. The average thickness of the developed and partly developed ore in this area,** as hereafter shown, is 345 ft. The entire orebody has been re-blocked and sectionalized, and the tonnages and values re-calculated upon a basis that is as definite and accurate as the character of orebody permits. After deducting all ore mined up to January 1, 1911, there remains in the area in which our principal development has been done, 203,500,000 tons of fully and partly developed ore. Of this amount 152,130,000 tons are fully developed and blocked. The **stated tonnage of developed and partly developed ore in**cludes 22,325,000 tons of partly developed ore in the slopes calculated to apply to steam-shovel workings, but outside of the ore area of 166.15 acres previously described. In calculating ore tonnages, 13 cu. ft. of ore in place is taken as one ton. Of the fully developed ore, 60,000,000 tons has an average copper content of 2%, and the remaining **92,130,000 tons of ore fully developed contain 1.6% copper.** The average assay of the partly developed ore is 1.4% copper. The entire 203,500,000 tons developed and partly developed ore contains an average of 1.67% copper. In obtaining these averages, there have been used the samples **from 225,722 ft. of drifts, raises, winzes, and drill-holes,** the total number of samples taken being 27,186. As a check against the average percentages of copper stated, it is interesting to note that the average assay of the total 11,175,916 tons of ore mined and milled from the Utah and Boston groups, prior to the date of this report, was 1.64% copper.

In connection with steam-shovel mining, it is difficult, if not impossible, to avoid the admixture of some lower-grade material with the ore. It is estimated that in the extraction **of the entire ore reserve stated, the average copper content will fall possibly as low as 1.6%; but, as steam-shovel** mining results in the loss of no ore, the lowering of grade from this cause is in a measure compensated by a corresponding increase in tonnage.

The average thickness of capping on that portion of the **Utah group now developed, is 80 ft. The best data at** hand on the Boston group indicates that the capping is **about 160 ft. thick, although further determinations may prove it to be somewhat thinner. Assuming 160 ft. as the thickness of capping on the Boston area so far developed,** the average thickness for the total developed and partly **developed ore of both groups is 105 ft., or a ratio of ore** to capping of approximately 3.3 tons of ore to one ton of **capping. During the year 1910 the total capping removed** from both the Utah and Boston areas was 2,814,764 cu. yd., of which 2,145,844 was removed from the Utah area, and 668,920 from the Boston area. Prior to the acquisition of the Boston group, 1,116,000 cu. yd. of capping had been **removed from that property. Prior to 1910 there had been** removed from the Utah group 3,231,792 cu. yd. of capping. Adding to this the yardage removed during the year 1910, makes the total capping removed from both groups to January 1, 1911, 7,162,556 cu. yd. **The total area upon which stripping operations have been conducted on both groups, and which is therefore either wholly or partly stripped, is** 85 acres. The actual area completely stripped on both groups is 20.87 acres, of which only 0.33 acre is in the Boston area. The total yardage removed from both areas represents the equivalent of completely stripping 11.67 acres of capping, of the average thickness previously stated, for the combined groups. Such an area would contain [illegible] tons of ore, the quantity of ore per acre, at the average thickness of [illegible] ft., being [illegible] tons. The previously stated total amount of ore removed from the mines is, therefore, approximately one-fifth of this tonnage.

Of the total ore mined during the year, 82% was mined by steam shovels from the Utah mine, and 18% by underground methods from the Boston mine. The average cost of mining for the year was 40.97c. per ton, of which 13.3c. was charged to cover development and stripping expense, leaving a total cost for producing ore of 27.67c. per ton. The total cost of producing 20% of underground ore was approximately the same as that of producing the other 80% by steam shovel methods. These costs include their proper apportionment of all fixed and general charges.

The Magna plant was operated continuously throughout the year. The Copperton plant was permanently closed on August 1, and has been dismantled, the machinery being taken to the Arthur (old Boston Con.) plant to be used in remodeling it. Portions of the Arthur plant were operated intermittently during the year, as the tonnage produced was in excess of the Magna plant's existing capacity. On November 1 three of the thirteen sections of the Arthur plant were permanently closed and partly dismantled, for the purpose of remodeling them along the lines of design, and for the methods of operation employed at the Magna plant. When the remodeling of the Arthur plant is completed, it will have a capacity of approximately 8000 tons per day, as compared to 3000 tons for the old plant. During the year the capacity of the Magna plant has been increased to more than 10,000 tons per day, and its metallurgical results have been improved. The total tonnage treated at all plants for the year was 4,340,245, of which the Magna plant milled 3,209,984 tons, the Arthur plant 936,900 tons, and the Copperton plant 193,361 tons. The average grade of the ore treated at all plants was 1.54% copper, and the average extraction at all plants 66.55%, equivalent to a recovery of 20.51 lb. of copper per ton of ore. The average extraction at the Magna plant, on the grade of ore stated, was 67.3%, and that of the Arthur plant, on the same grade of ore, 64.41%. The improvements in the Magna plant have resulted in a gradual betterment in its metallurgical results, until at the close of the year it is making an extraction of about 70% on this grade of ore. The average cost of milling for all plants for the year was 46.63c. per ton. The average cost of milling at the Magna plant was 43.76c. per ton, and that at the Arthur plant 51.34c. per ton, these milling costs including their proper proportions of all fixed and general charges.

The total production of all plant for the year, of copper contained in concentrate, was 89,019,511 lb. The average grade of concentrate produced was 27.28% copper. The average price received for copper sold during the year was 12.672c. per pound. The average cost per pound of copper produced, based on the net pounds of copper resulting after smelting deductions and allowances were made, and after applying credits for the gold and silver recovered, was 8.069c., as compared to 8.787c. for the year 1909. This cost includes all expenses of smelting, refining, transportation, and selling the metal. The average cost of production at the Magna plant for the period, and on the same basis, was 7.8828c. per pound. During two months of the year, September and December, on an average grade of ore for those months containing only 1.43% of copper, the Magna plant produced copper from this lower-grade ore at a net cost of 8.5c. per pound. The average total cost of mining and milling, exclusive of transportation charges, was 87.6c., as compared with 94.43c. for the previous year. Included in this cost is the charge previously referred to, under the discussion of mining, of 13.3c. per ton, covering all underground development costs at the mine, and a proper proportion of stripping expense. Economies now being effected are expected to materially decrease costs during the next fiscal year.

Book Reviews

Any of the books noticed in these columns are for sale by or can be procured from, the MINING AND SCIENTIFIC PRESS

APPLIED ELECTROCHEMISTRY. By M. deKay Thompson. 325 pp., ill. The Macmillan Company, New York, 1911. For sale by the *Mining and Scientific Press*. Price $2.10.

In gathering together in one volume the scattered results of the recent developments of electrochemistry, Mr. Thompson has done useful service. The criticism may be leveled at his volume by electrometallurgists that too much space has been devoted to theory and too little to the discussion of practice, but an author is his own best judge of what he wishes to discuss, and in this case he does not claim to have produced a work intended to cover the subject in all its phases. Many engineers will welcome his treatment of the electrometallurgy of iron; the storage battery and the electric furnace are discussed, and cyanide metallurgists will find much to interest them in the chapter on the fixation of atmospheric nitrogen.

HANDBOOK OF THE PORCUPINE DISTRICT. By H. P. Davis. 131 pp., ill. 25 Broad street, New York. For sale by the *Mining and Scientific Press*. Price $1.

This is a companion to the handbook of the Cobalt district, by the same author, and contains a brief historical sketch and an outline of the geology of the district, leading up to the chief feature, a directory of the incorporated companies and operating syndicates of the district. This is followed by a review of the Cobalt district and a brief discussion of the South Lorrain, Montreal river, and Gowganda districts. Six pages of general information for prospectors and mine-owners, and a fairly good index complete the book. It is well illustrated, printed on good paper, and will prove a useful book of reference to all those who are interested in this promising new district.

GOOD ENGINEERING LITERATURE. By Harwood Frost. 422 pp. Chicago Book Co., 1911. For sale by the *Mining and Scientific Press*. Price $1.

This is not a check-list of engineering reference, as might be inferred from the title, but is a general text on literary expression, what to write about, how to write, the processes of publishing, and the art of literary criticism. The beginner can derive much benefit from the study of this volume, for it is written in an elementary style, and some parts of it are a compilation of what others have written upon the subjects under discussion. The author is conscientious and gives full credit to those whose material he has made use of, but his choice of a misleading title indicates that he is not a master of the literary art, and his first page amply confirms that inference. In spite of, or perhaps even because of, that fact, his work will be of great service to the many poor writers in the engineering profession, and is one of the best of the low-priced publications on the art of writing and of book-making.

THE PRINCIPLES OF SCIENTIFIC MANAGEMENT. By Frederick W. Taylor. Harper & Brothers, New York, 1911. For sale by *Mining and Scientific Press*. Price, $1.50.

In this little volume Mr. Taylor gives the deductions as to the principles of works management derived from his wide and comprehensive experience, during which he has made several series of scientific experiments to obtain the data upon which his system is based. The author, as a scientific man, can scarcely intend to give the impression that the amount of experimental work which he has done is sufficient to base a complete system upon, but he has disclosed broad lines along which to work, and the book would be worth while if it did nothing more than emphasize the necessity for definite data as to efficiency in work and what really constitutes a day's work, in place of the vague general ideas, derived in haphazard fashion, that often are the only guides of the management. There is much more to the book than this, and whether the reader agrees with the author in all cases or not, he can not fail to be stimulated by what Mr. Taylor has to say.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

Action to Recover Possession of Mining Ground—Remedy by Appeal

Any error of a court in ordering judgment for plaintiff for possession in an action to recover possession of certain mining ground under an agreement providing that the complainant might take possession of and work the mines, is reviewable by appeal only, and cannot be inquired into by a writ of prohibition.

Silver Peak Mines *v.* Second Judicial District Court, (Nev.), 110 Pac., 503. Aug. 1910.

Deed for Coal and Mining Privileges—Right to Subjacent Support

Where a deed conveys the coal under a tract of land, together with the right to enter upon and under the land, and to mine, excavate, and remove all the coal under such land, there is no implied reservation in such a deed that the grantee shall leave coal enough to support the surface in its original position, but on the contrary is a waiver or surrender of such right, and the grantor cannot recover damages for injury to the surface resulting from the removal of all the coal without leaving sufficient support.

Kuhn *v.* Fairmont Coal Co., 179 Federal, 191.

Death of Miner by Suffocation—Assumption of Risk

In an action for damage for the death of a miner caused by suffocation it is proper to prove that the superintendent directed the miner to enter the mine and told him that it was perfectly safe. And such evidence is competent in determining the question of assumption of risk and contributory negligence on the part of the miner. And where the miner was informed by a third person in the presence of the foreman that it was safe to go into the mine and the foreman immediately directed the miner to go ahead that everything was all right, the court cannot say as a matter of law there was existing a degree of danger calculated to deter a person of ordinary prudence from the undertaking, and such as to make him guilty of contributory negligence in going into a mine.

Alabama Consolidated Coal & Iron Co. *v.* Healds, Alabama 53 Southern, 162.

Statute Limiting Power of Directors as to Purchase of Additional Mineral Ground

The statute of California provides that directors of a mining company shall not sell, lease, mortgage, or otherwise dispose of the whole or any part of mining land owned by the corporation, nor shall they purchase or obtain in any way, except by location, any additional mining land, unless the action of the board be ratified by the stockholders of at least two-thirds of the corporation stock then outstanding. In the application of this statute, the Supreme Court of that State decided that it went to the power and authority of the directors to act, and not merely to personal liability of such directors, and a mortgage of the mining lands of a mining corporation executed by the directors in the absence of such a ratification by the stockholders passed no title to such lands. But the particular form of ratification provided by the statute is not exclusive, and it is sufficient where the holders of the requisite majority of the stockholders had in some formal and unequivocal way announced their assent to the proposed mortgage; and all stockholders of record holding stock for lawful purpose, though not the beneficial owners thereof, are stockholders within the meaning of this statute. However, in the absence of such a ratification, neither the corporation itself nor any stockholder may raise the question of the invalidity of such mortgage.

Royal Consolidated Mining Co. *v.* Royal Consolidated Mines Co., (Cal.) 110 Pac., 123.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. S. Noyes has returned from Oregon.

E. A. S[illegible]erry has left for China.

W. C. Greene was in San Francisco last week.

Charles Janin has gone to southern California.

A. K. Beatson, of Oakland, was recently in Nevada and Utah.

E. J. Collins has been in San Francisco during the week.

Fred L. Lowell has returned to San Francisco from Mexico.

J. Parke Channing is motoring near Lenox, Massachusetts.

R. J. Cannon has been visiting the dredging fields of California.

R. S. Botsford has arrived in London from Rio Grande do Sul, Brazil.

H. F. Bain is returning to Seattle from Juneau, on his way to Valdez.

Lionel Lindsay sails for England today from Guaymas, by way of Tehuantepec and Cuba.

Courtenay De Kalb was in San Francisco on Wednesday and will return to Mexico in about ten days.

Howland Bancroft will be in South America until about October 1; he will visit various mining districts in Peru, Bolivia, and Chile.

Oliver B. Finn will be several weeks near Twin Lakes, in Lake county, Colorado, doing some examination work on a dredging placer.

Arthur J. Hoskin has resigned from the faculty of the Colorado State School of Mines and has opened an office in the Commonwealth building, Denver.

S. B. Flagg and C. D. Smith, of the Bureau of Mines, presented a paper on the work of the Bureau at the meeting of the American Society of Mechanical Engineers, Pittsburg.

Earl C. Galbraith, a recent graduate of the Mining Department of the State College of Washington, has been appointed Mineral Examiner to the United States Land Office and is stationed in Montana.

Obituary

Andrew V. Corry, born in Maryland in 1837, a miner at Georgetown, Colorado, in its early days, and a resident of Montana for 48 years, died at Butte early in June. He was engaged in placer mining on Alder gulch, Virginia City, in 1863-5, and later became a resident of Butte, where he acquired interests in mines.

John Y. McKane, an engineer well known especially in Nevada, at Goldfield and Tonopah, died recently in San Francisco from congestion of the lungs. Mr. McKane was born in Scotland and some years ago returned to his native heath to live. While in San Francisco on business he was stricken with a brief and fatal illness. He was a man of wide business interests and leaves a large circle of friends.

Technical Schools and Societies

The senior class of the Mining Department of the State College of Washington, recently completed a tour of the mining camps of Washington and British Columbia. The class was accompanied by Francis A. Thompson, head of the department, and visited the mines and mills of Republic, Washington, the smelters and mines of the Boundary country, and the Consolidated properties and plants in Rossland and Trail, in addition to other points of minor interest.

Market Reports

LOCAL METAL PRICES

San Francisco, June 29.

Antimony	11—12½c	Quicksilver (flask)	46

Firebrick:		
Bauxite, per M	175.00	
Magnesite, per M	190.00	275.00
Silica, per M	42.50	47.50
Flint pebbles for tube-mills, per 2240 lb	15.00	25.00
Fluorspar, per ton	10.00	15.00
Fullers earth, according to quality, per ton	20.00	30.00
Gilsonite, per ton	35.00	40.00
Graphite:		
Amorphous, per lb	0.01	0.02½
Crystalline, per lb	0.04	0.13
Gypsum, per ton	7.50	10.00
Infusorial earth, per ton	10.00	15.00
Magnesite, crude, per ton	7.50	10.00
Magnesite, dead calcined, per ton	22.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	40.00	120.00
Mica, according to size and quality, per lb	0.05	0.30
Molybdenite, 95% MoS_2, per ton	400.00	500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per 100 lb.	2.25	3.25
Platinum, native, crude, per oz	30.00	40.00
Scheelite (see tungsten ore).		
Sulphur, crude, per ton	15.00	25.00
Talc, prepared, according to quality, per ton.	20.00	50.00
Tin ore, 60%, per ton	450.00	475.00
Tungsten ore, 65%, per ton	487.00	520.00
Vanadium ore, 15%, per ton	200.00	250.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	*15.00	20.00

Commercial Paragraphs

The Kennicott Co. of Chicago, Ill., has recently secured an order for a self-supporting steel stack 13 ft. in diameter and 205 ft. high, for the Kentucky Electric Co., Louisville, Kentucky.

H. A. Hunt has been appointed Eastern sales agent of Edgar Allen American Manganese Steel Co., with headquarters at New Castle, Del., which appointment was made in order to fill the vacancy caused by the resignation of V. W. Mason, Jr.

Falkenburg & Laucks, Seattle, Wash., have a physical laboratory in connection with their ore-testing plant, containing a Reihle machine of 200,000 lb. capacity for making tensile tests of iron and steel, and compressive tests of bricks, concrete cubes, and stone.

The Goulds Manufacturing Co. of Seneca Falls, N. Y., is about to build four large additions to the No. 2 plant, in which will be housed the part of the works known as the No. 1 plant, a portion of which must be torn down to make way for the new barge canal.

Allis-Chalmers Co. announces the appointment of G. T. Hansen as manager of its Salt Lake City office. Mr. Hansen has been connected with the Allis-Chalmers Co. for several years in the capacity of metallurgical engineer and has had a wide and varied experience in the mining field, both in this country and in Mexico.

The Electric Weighing Co. has been formed to manufacture and sell the Messiter weighing machine. This apparatus is used for weighing moving loads on belt or bucket conveyors. A recent installation was made of two of these machines at the Nevada Consolidated Mining Co.'s mill. The factory and office of the Electric Weighing Co. are at 180 13th avenue, New York City.

O. H. Johnson is now a salesman with the Mine & Smelter Supply Co. For the last five years Mr. Johnson has been identified with the engineering and sale of some of the most prominent plants and mills in Utah, Nevada, and Idaho, among them being the Goldfield Consolidated, Farmers Mining, Bagdad-Chase Gold Mining, Geo. F. Roth Mining, Inland Crystal Salt, and many others.

On June 1, 1911, the Fort Wayne Electric Works was merged with the General Electric Co. of Schenectady, N. Y. Its business will be conducted under the name of Fort Wayne Electric Works of General Electric Co. The same lines of apparatus and supplies will continue to be manufactured and sold under the immediate direction of the same individuals as heretofore, with F. S. Hunting in responsible charge as general manager.

The Ellsworth Collieries Co., which operates considerable mining property at Ellsworth, Pa., will install a central plant for generating and distributing electric power to its several mines. With this end in view, it has ordered of the General Electric Co. one 750-kw., 60-cycle, 2300-volt generator, driven by a mixed-pressure Curtis turbine; one 360-kw., 60-cycle, 2300-volt belt-driven generator; one motor generator exciter, one belted exciter, and switchboard.

R. B. Woodworth, engineer for the Carnegie Steel Co., read an interesting paper on steel derricks and drilling rigs before the sixth annual convention of the Natural Gas Association of America, which was held at Pittsburg in May. The paper has been published in the *Proceedings* of the Association together with illustrations and data that will be particularly interesting to well-drillers and oil operators. Mr. Woodworth has gone into the matter most thoroughly and added a valuable contribution to literature on this subject.

The Santa Rosa Mining Co., a subsidiary of the Exploration Company of England and Mexico, situated in the State of Zacatecas, Mexico, near Concepcion del Oro, has received and is erecting most of the machinery for its mill. All of the equipment has been purchased from the Cia. Ingeniera, Importadora y Contratista, S. A., of Mexico City, which has furnished Westinghouse equipment throughout. The motors are of a new type which the Westinghouse company has brought out for especially heavy duty service. When completed, this property will have one of the most modern equipments in Mexico.

In an article now in preparation, the Foos Gas Engine Co. will give out data collected from actual power-plant experience with its engines operating on petroleum and distillates. Advance reference to this bulletin shows a reliablility and economy that makes the most economical gasoline engine a luxury. In proof of this, comparison is made between a Foos engine using kerosene at 5c. per gallon and a gasoline engine using 12c. fuel. A 10-hour day with a 25-hp. oil engine at full load shows a fuel cost of $1.55. A gasoline engine under the most favorable conditions would use 31¼ gal. of fuel, which at 12c. would cost $3.75. A total saving for 300 working days would give the oil engine a lead of $660 per year. As a matter of fact, the advantage in favor of the oil engine is shown to be even greater. Kerosene can be bought as low as 4c., and in many fields oils are available at 2¼c. The Foos company claims that nothing is sacrificed to gain this economy, and that 25 years experience enables it to produce an oil plant with all the durability and reliability of a steam-engine. The new literature on this subject will be known as 'Oil Bulletin 92'.

THE FLOTATION PROCESS

CAN BE

SUCCESSFULLY APPLIED

First:

Where the mineral values of material to be treated, whether crude ore, tailing, or slime, are **friable** and wet concentration fails to catch the flat or lenticular metallic particles which float away.

Second:

Where the metal contents to be saved and the gangue or waste are of so nearly the same specific gravity that **the separation is crude** and sometimes wholly ineffectual by wet concentration.

These two conditions are found often in zinc, lead, silver and copper ore, and in the tailing and slime rejected in treating ore containing these metals.

THE FLOTATION PROCESS

AS OWNED AND PERFECTED BY THE

MINERALS SEPARATION, LTD.

has been highly successful in Australia, and over **one million tons** of **crude ore, tailing,** and **slime** are treated annually.

This company has now fully covered their apparatus and process by no less than fifteen separate patents, granted by the United States, and also by Mexico and Canada.

Mine owners, metallurgists, and others interested in preventing sulphide losses, and reducing the cost of treatment, are invited to send their enquiries

TO

Minerals Separation American Syndicate, Ltd.

Sole Agents:
MESSRS. BEER, SONDHEIMER & CO. Chief Engineer: E. H. NUTTER
42 Broadway, New York

NOTE.—Notice is hereby given that no one except our Chief Engineer and the Agents named above is authorized to act for or represent the Minerals Separation, Ltd., or to introduce their processes or apparatus into the United States, Canada and Mexico.

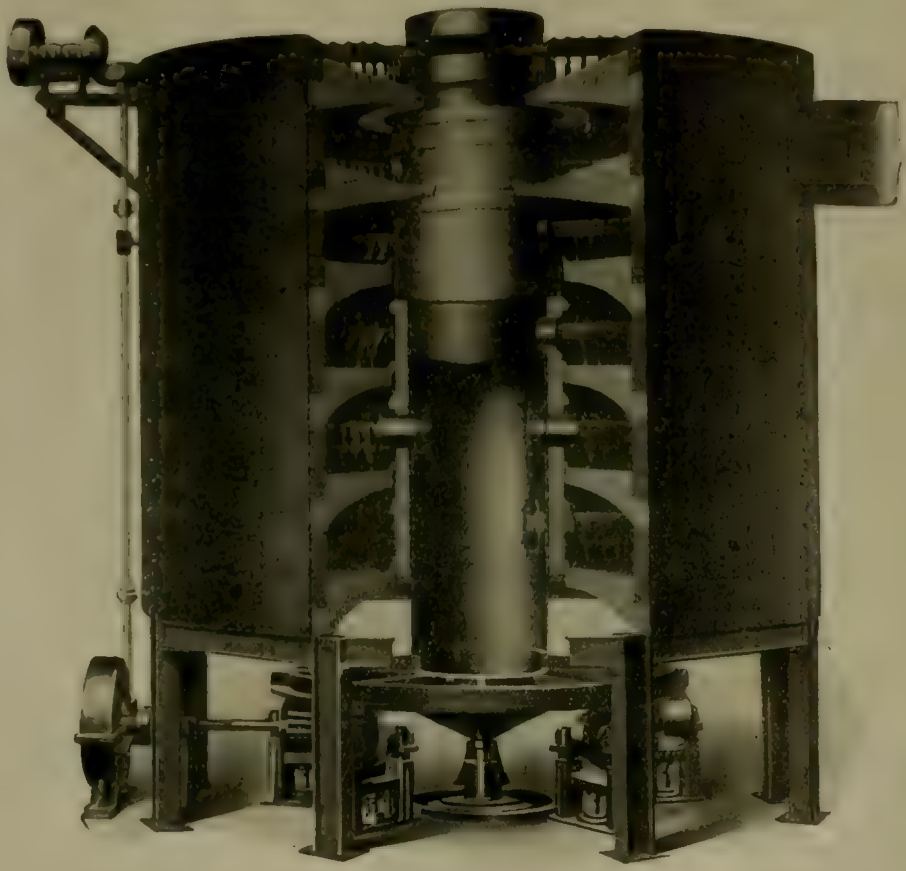
The Wedge Mechanical Furnace

PATENTED



YOU CANNOT AFFORD TO IGNORE IMPROVEMENTS

As the successful high recovery of values depends to a large extent on securing a proper roast, it will pay you to install Wedge Furnaces.

Write us, stating analysis of ore, concentrates, mixture or material you desire to roast, characteristics and physical condition of same, number of tons to be treated per twenty-four hours, and results you desire in the calcine.

WEDGE MECHANICAL FURNACE COMPANY

GREENWICH POINT, PHILADELPHIA

HARTLEY, J. H.,
Mining Engineer.
Manager Compania Minera del Porvenir, San José, Costa Rica.
Cable: Hartlo. Code: Bedford McNeill.

(CONTINUED ON PAGE 14.)

Re Results!

Hydrochloric Acid Wash Nonsense

Having Been Disposed Of

Witness the performance of the Type "A" Moore Filter month in and month out in
PACHUCA, MEXICO

Monthly average, values discharged in tailings:

SAN RAFAEL,
Capacity 500 tons daily, 6 **cents** per ton.
SANTA GERTRUDIS,
Capacity 200 tons daily, 5 **cents** per ton.
LA BLANCA,
Capacity 300 tons daily, 5 **cents** per ton.
LA UNION,
Capacity 100 tons daily, 6 **cents** per ton.

Three additional Type "A" plants nearing completion.

Average **annual** "upkeep" of Filter Cloths, **two one hundreths** of a cent per ton of slime treated.

Do you wonder why we so strenuously urge you to adopt the "Type A" or "Movable" method of working the Moore Process, in preference to the "Type B" or "Stationary," much less the other types "C" (Pressure), "D" (Rotary), "E" (Revolving Drum), all of which in the order named are inferior to the "Type A?" If you are still skeptical, do as we have done, invest a few dollars in obtaining average samples of the tailings dumps from these other types, and assay them. As might be expected infringing the "Type A" would appear too flagrant, hence you are offered the less effective methods by infringers, and put together in such a way as to amount to little more than the ordinary de-waterers.

The difference in efficiency **more** than compensates for any consideration that we ask for the right to use the Moore Process.

The Moore Filter Company

Special Announcement

We have recently secured the exclusive agency for the Balata Conveyor Belting manufactured by R. & J. Dick, Ltd., Passaic, New Jersey.

The DICKBELT was the original and remains the standard of this type of conveyor belting. It is stronger and tougher than any other belting made: it is unaffected by moisture and it does not deteriorate with age.

This belt, together with our "S-A" Special Rubber Conveyor Belting and our "S-A" Oiled and Stitched Conveyor Belting, forms a trio of the highest grades of conveyor belting manufactured, from which we are able to choose for our customers the belt best adapted to their needs.

Our only interest in advising the use of any particular one of these belts for a special use is the resulting economy of the installation, upon which depends our own success.

The above illustration shows an "S-A" Conveyor discharging copper ore over an "S-A" Movable Tripper into the storage bins of the Boston Consolidated Mill (now the Arthur Plant of the Utah Copper Co.), Garfield, Utah. A large amount of "S-A" Conveying Machinery which was used in this mill has given excellent service for several years.

Where difficult conveying problems are encountered, or advice is needed as to the best practice, our engineers are glad to sketch out an efficient solution.

Sales Talks on ROCK DRILLS

Standard "Sergeant" Independent Valve Drill.

11—The Law of Averages

With all the care and with the best facilities in the world, no manufacturer can maintain an absolutely perfect product.

We have built and sold individual drills which have "fallen down" most disgracefully, from no apparent cause. And we have made them good.

But in the long run, year after year, these exceptions prove to be so rare that our confidence is in no wise shaken.

Averaged month after month, and year after year, experience in hundreds of cases has shown that there is actually more work capacity in the average Ingersoll-Rand Rock Drill than in even the exceptionally good other ones.

Hence we say that the law of averages throws the weight of evidence on the side of Ingersoll-Rand Rock Drill supremacy.

CONTINUOUS DECANTATION

WITH

DORR THICKENERS

Cyanide Plant Erected by the United States Reduction & Refining Co. at Colorado City, Colo.,

To treat a half million tons of low grade tailings where extreme efficiency and low operating cost were essential.

This plant of 400 tons capacity is recovering the dissolved values by means of a series ot settlings and dilutions carried on continuously in four tanks equipped with Dorr Thickeners, and is discharging residues containing 65-70% solids.

Continuous operation made possible by the use of Dorr Thickeners, results in increased capacity with decreased cost for equipment, power, labor and supplies.

This method was selected as the most economical way of treating this very low grade tailing.

Continuous decantation is in use at the Vulture Mine, Wickenburg, Ariz., for reducing the value of the solution in the pulp before filtration, and is now being installed for the same purpose at the Nevada Hills Mill, Fairview, Nev.

It is used without filters, as in the plant shown above, at the El Palmarito Mine, Mocorito, Sinaloa, Mexico, where the tailing is discharged with only **30%** moisture. The ore treated is a quartzite ground through 150-mesh.

We shall be glad to send you additional data. Or if you will submit data on any prospective plant we will give you a definite statement of results to be expected from Continuous Decantation with Dorr Thickeners.

INDUSTRIAL LOCOMOTIVES

American Locomotive Company's light locomotives meet every requirement of contracting, quarrying, mining and industrial service.

They are produced by men of skill and judgment in design, whose specialty is the building of locomotives for every kind of hauling. Back of the individual experience of these men is a record of over seventy-five years of continuous success in locomotive building for railroads in every part of the world.

The small locomotives are of the same high grade as those built for the standard railroads. This high quality of material and workmanship insures long, continuous service. This means high earning capacity.

All the parts are made in jigs so that they are absolutely interchangeable between engines of the same class. Duplicate parts are kept in stock at our works at Paterson, New Jersey, and in storehouses in Chicago and San Francisco.

Tell us your requirements, and we will give you a price on a locomotive exactly suited to your needs.

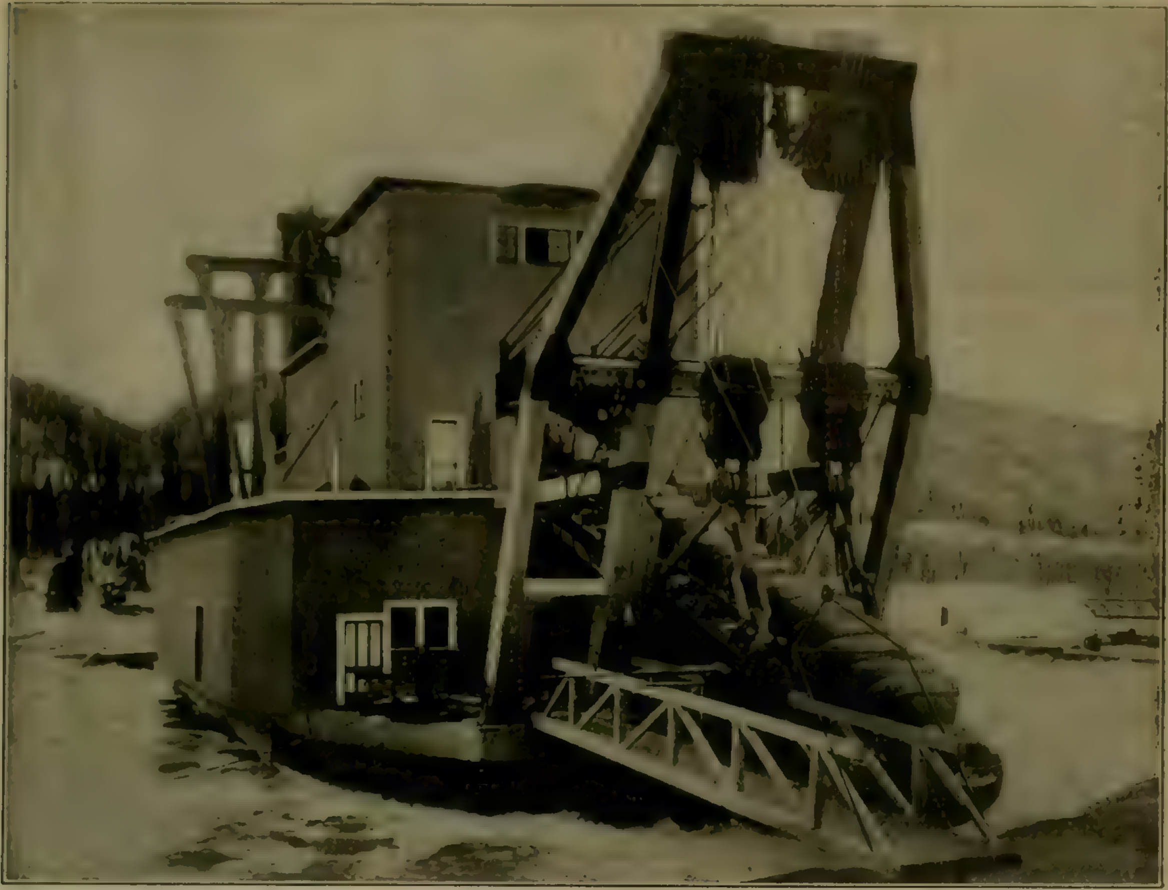
MARION ELEVATOR DREDGES



"CANADIAN"—The 16 Cubic Foot Elevator Dredge built by us for the Canadian Klondyke Mining Company, Ltd.

Vital Points Which Mark the Difference Between Success and Failure in Placer Mining

In elementary design all gold dredges are somewhat alike.

The difference comes on what may seem secondary features, which, however, are really vital.

These include the perfection of detail.

The design and method of construction of essential features—

And quality of materials.

Important among the reasons for the Marion Elevator Gold Dredge's efficiency is the fact that practically its every part is made in our own plant.

We even have our own open hearth steel foundry to make special parts of selected material.

How the Marion Dredge is built in detail—

How it solves the problem of working in cold climates and handling a maximum output of hard gravel cannot be explained here.

Our Catalog, however, with descriptions, and illustrations of parts and photographs of Dredges in operation, does explain it to you.

We'll be glad to send you a copy.

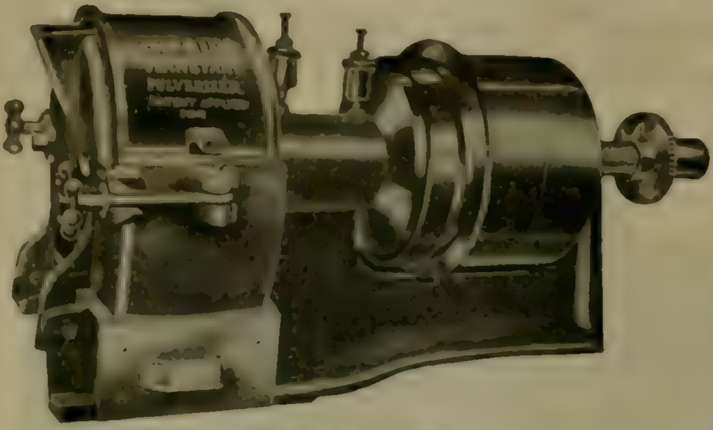
BRAUN PLANETARY PULVERIZER

THE PERFECT LABORATORY GRINDER



(PATENT APPLIED FOR)

This machine, in addition to the **centrifugal motion** as obtained in the regular BRAUN PULVERIZER (with which nearly every laboratory operator is acquainted), imparts a **planetary movement** to the disc, insuring a successful machine for grinding all classes of material, whether hard, soft or talcy.

Delivers a uniform product with one grinding.
Capacity — 1 pound — 40 seconds — 80 mesh — when pulverizing medium hard quartz.

SPHERICAL OR CERRO DE PASCO TYPE OF CONVERTER

THE Spherical type of converter illustrated above is eleven feet in diameter and will turn out two and a half times as much copper, per lining, using same grade of matte and character of lining as standard type of barrel converter. Larger charges, both initial and subsequent, can be blown. Matte receptacle instead of rectangular section as in the barrel type is round or elliptical, which provides an arched lining as in an upright type of converter.

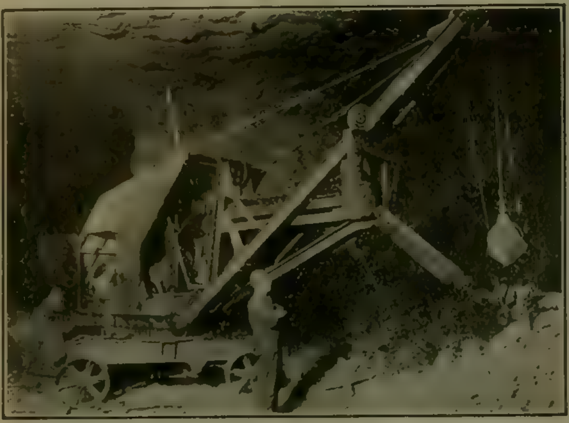
75 Fremont Street :: :: :: San Francisco, Cal., U. S. A.

Thew Shovels for Underground Mining

Because of its horizontal dipper crowding motion, the THEW shovel can be employed in underground work with overhead clearances as low as 10 feet by making use of a special design for boom. The full circle swing of the THEW shovel permits its convenient use under usual mining conditions. The machines may be mounted either upon car wheels or traction wheels and may be equipped for operation by compressed air or electricity.



Zinc Ore Mining at Joplin.

Thew Shovels

of the FULL CIRCLE SWING type are built in six standard sizes, ranging from 12 to 50 tons in weight, and from one-half yard to two yard dipper capacity.

Numerous modifications have been made to adapt the shovels to special conditions or to render the machine available for service of a miscellaneous nature.

AS TO QUALITY

we refer to any owner of any THEW shovel anywhere.

Shovels for All Classes of Mining Operations

Underground mining or surface work, open cuts, ditch construction or rehandling tailings.

THE THEW AUTOMATIC SHOVEL COMPANY, LORAIN, OHIO

Dredging for Gold and Tin

ARCTIC GOLD DREDGING CO.'S DREDGE No. 1.
On Saunders Creek, Nome, Alaska.

This dredge has buckets of 2¾ cu. ft. capacity and is driven by gasoline engines, consuming a maximum of 150 gals. of No. 1 engine distillate in a 24-hour run. This dredge was designed by the Union Construction Co. to meet local Alaskan conditions, and the cost is moderate.

Requires: first, a certain set of conditions in the property to warrant dredging; second, a dredge designed and built to meet those conditions.

Most failures in dredging have been due to the installation of improper equipment. We are experts in the design and construction of dredges and invite your inquiries.

UNION CONSTRUCTION CO.

H. G. PEAKE 604 MISSION ST., SAN FRANCISCO, CAL. W. W. JOHNSON

Let Us Help You Finance Your Placer Proposition by Furnishing an

"EMPIRE" DRILL

"Empire" Drill with Spring Drilling Attachment.

The demand for good placer ground is steadily growing. Many prospecting parties are being sent out by large syndicates, equipped with "Empire" Prospecting Drills, to test placer properties.

If you have a placer proposition, you will have no difficulty in raising capital for equipment, or in selling outright, if you prove your ground with an "Empire" Drill.

Drill your ground with an "Empire" Drill. Submit your results to us and we will help you in exploitation.

Our principal interests lie in gold dredging, which we are developing on business lines. If you prove your ground with an "Empire" Drill, giving accurate results, we can help you in the financing.

We are dredging ground tested with an "Empire" Drill, the dredging returns from which check within two per cent of the drilling indications.

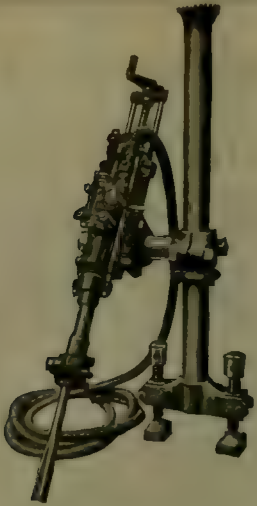
"Empire" Prospecting Drills and "Empire" Gold Dredges have reduced placer mining to a science. The certainty of results is not equaled in any other business.

An "Empire" Gold Dredge at Work.

"Empire" Drills are in stock in all the placer mining centers of the world.

NEW YORK ENGINEERING CO.

2 Rector Street, New York City



Kaffirs Make Drill Records With Holman Rock Drills

When unskilled Kaffir labor can make low cost records with Holman Drills—you can readily appreciate why we say that Holman Drills can lower drilling costs for you.

Easy to operate, strong, well built, capable of standing the roughest kind of handling without falling down on the job, Holman Drills make drilling records wherever they are used—

Regardless of the kind of rock, the kind of labor, or the pressure.

The whole construction, based upon conditions that actually exist under ground, is so far superior to other types of drills that we positively guarantee Holman Drills, over long periods—

To drill a greater footage at a lower cost for air and repairs than any other make of equal size.

Our Catalog describes the Holman 1911 Model in detail. Write for a copy.

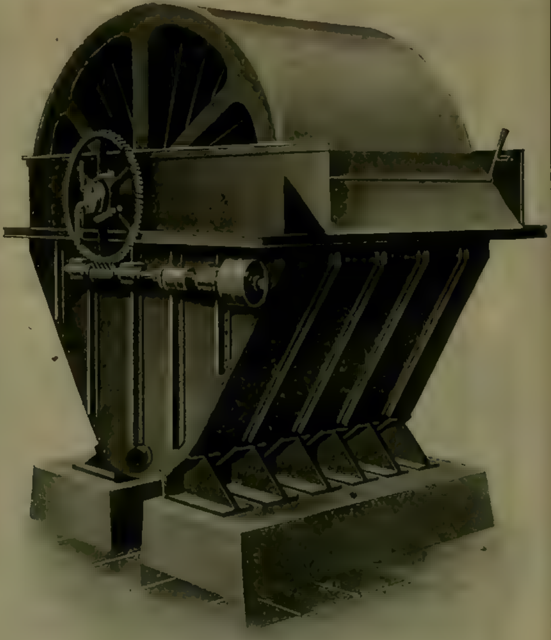
AGENTS—The Mine & Smelter Supply Co., Denver, El Paso and Salt Lake City. Mussens, Limited, 318 St. James St., Montreal, Canada. Chas. Butters, Apartado No. 1578, Gante No. 1, Mexico, D. F. Fraser & Chalmers, Ltd., London, Johannesburg, Bulawayo. The Australian Metals Co., Melbourne.



The Oliver Filter

as told by the users.

Economy of Operation—

"The costs of operating the filters and slime plant *combined* is now less than the slime plant cost *alone* before the installation of the filters—due to decrease in cyanide consumption and in power."

"The total costs for labor, power, cyanide and supplies have been reduced from $1.20 to $0.80 per ton—a saving of 35% in working costs."

—*Excerpts from Mexican Correspondence.*

Extraction—

"It is handling a high grade, refractory silver ore, the greater part of which passes 150 mesh screen. This ore is quite variable in texture, consisting of quartz, spars, and a considerable amount of talc.

The *filtered solution* averages *6 oz. silver* and the efficiency of the filter on this grade of solution is 99.3%. This is obtained with a 20″ vacuum by a dry pump running at 165 R. P. M. and giving a 21″ vacuum on closed throttle."

—*From a custom mill operating at 6000 ft. altitude.*

Names of the above correspondents will be furnished prospective purchasers.

These results can be duplicated in your plant.

ROBINS BELT CONVEYOR

The Engineering Staff of the Robins Company have been successfully solving conveying problems for fourteen years and the benefit of their experience is at your command.

The Robins Belt Conveyor was the Original and is to-day the Standard of this type of conveying machinery.

The designs and construction of Idlers and Belt are the result of fourteen years' manufacturing experience and they are superior.

It is successfully and economically conveying ore, rock, coal and similar materials under the most trying conditions of service.

Correspondence invited.

SCIENTIFIC MANAGEMENT

involves the use of the

Merrick Weightometer

in the modern Mine, Ore or Coal Handling Plant!

This is a Conveyor Scale Designed to *Automatically Weigh* and *Register Materials* of any kind **Whilst They are in Transit** over Belt, Bucket or other Conveyors.

It can be used to automatically—

Register ore as conveyed from mill storage bins to ore mill, thus keeping tally on the daily work of the mill;

Register ore, coal or rock shipped from mines or quarry, thus obtaining a continuous record of the amount produced and delivered;

Weigh and record coal or other raw material into a plant, thereby checking shippers' weights and keeping tab on receipts and amount of stock on hand, or amount taken from stock;

Weigh material in process of treatment, thus preventing under-production.

The machine weighs the continuous unbroken flow of material.

It takes up small space and has no complicated mechanism.

Tested and O. K.'d by U. S., British and Canadian Governments as a satisfactory medium of registering material carried on belts.

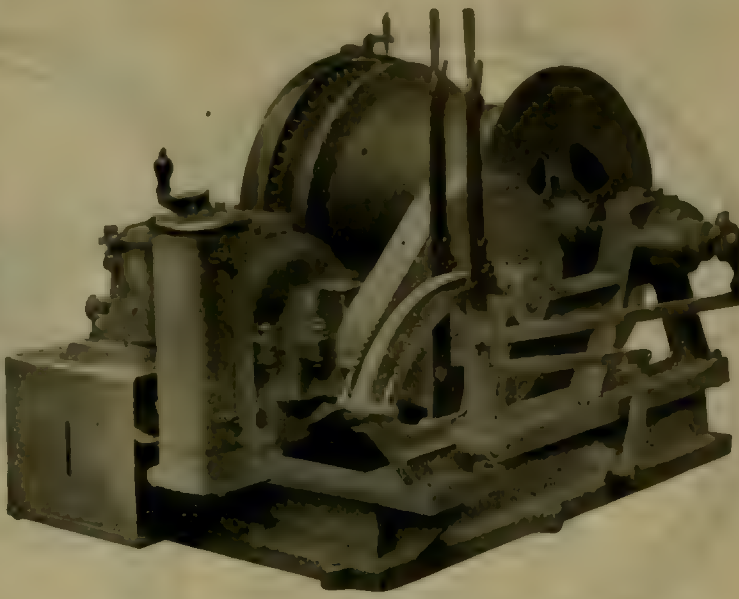
421 Sheldon Building, San Francisco, Cal.

Save Four-Fifths Of Your Power In That Winze

The average mining man places a small steam hoist or pump in an underground winze and drives it by compressed air. Under such conditions it may easily take 100 i.h.p. at air compressor to do the work of a 20 h.p. motor. If it is necessary to maintain air pressure outside of working hours the efficiency may fall to about 1 per cent.



In one case a steam engine of a hoist was replaced by a 50 h.p. 3 phase induction motor which paid at the rate of 15 per cent a year on the investment.

General Electric Company ITC Motors

are made especially for this service to stand overloads, moisture and dirt when operated by unskilled labor.

Complete Hoists of the friction drum, drum operated by jaw clutch, fixed drum with clutch pinion, or band friction drum types are furnished of the latest and sturdiest types in all sizes. Hoists as large as 1,100 h.p. are now in successful operation with the General Electric Company's equipment.

Mine Hoists And Pumps as recommended by the General Electric Company, are best because they represent years of careful study by men who have equipped many of the largest mines in the world. The records of these installations are before them when your problems are studied.

YOU CAN COUNT THE SAVING IN COLD CASH

Wouldn't you consider a rock drill that will save from 70% to 90% on cost of power? That's just what we claim the Fort Wayne Electric Rock Drill will do and can prove it. It takes but 1 1-2 horse-power against 10 to 15 horse-power for the corresponding size air drill.

Fort Wayne Electric Rock Drill

The Fort Wayne will not only save you power, but will advance your work faster, easier and better than ever before.

Can be installed anywhere an electric wire can be run, either above or below ground, at one-third the cost of pipe lines.

It has many exclusive features, such as impossibility of drill steel sticking in loose or broken ground, self-clearing steel which requires no water for sludging on flat or up holes, ability to change quickly from D. C. to A. C. current, etc. No flexible shafts, solenoids, etc., to get out of order. Bulletin 1120 describes and illustrates the design, construction and operation in detail. Send for it.

THE LEYNER BULLETIN

July 1 Littleton, Colo., U. S. A. 1911

In the Frozen North

THE SUPERIORITY OF WATER LEYNER DRILLS IS APPRECIATED, as the following extract of letter from Alaska testifies:

"We purchased one of your Model 6, No. 7 Drills as an experiment, to see if it was possible to reduce the cost of point driving.

Point driving is our big expense, and, thanks to your machine, we are enabled to make a 50% saving.

The No. 7 with two men is doing the work of six to eight point-men. The machine is being operated by inexperienced runners.

Our experiment has been watched with a great deal of interest by the mining operators of this district, who have their profits reduced to a minimum by the present method of point driving.

Your machine will be one of the big helps in reducing expenses."

NOTE.—Point driving is a system of drilling and thawing frozen gravel. A hole varying from 8 to 18 feet in depth is drilled. A sweater is then inserted and a small amount of steam turned into the hole, until the gravel has thawed. One steaming will usually thaw the gravel to six feet.

The gravel is then removed by pick and shovel to frost and the thawing operation repeated.

Water Leyner Drills have yet to encounter ground that they cannot drill faster and more economically than any other type.

WRITE US YOUR PROBLEM AND LET US TELL YOU HOW YOU CAN OBTAIN MAXIMUM FOOTAGE AT MINIMUM LABOR, POWER AND UPKEEP EXPENSE.

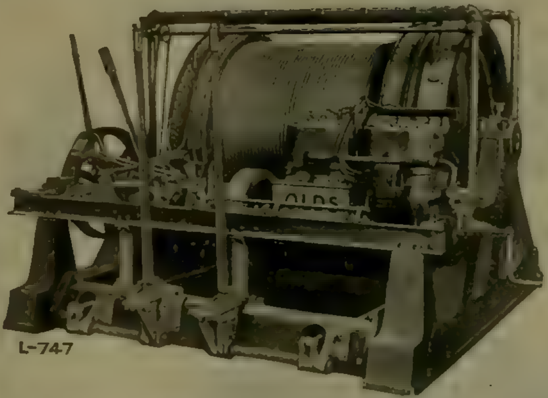
OLDS-CLOSE MINE HOIST

(Gasoline or Distillate)



San Carlos, Arizona, August 16, 1910.

Olds Gas Power Company,
Los Angeles, Cal.

Gentlemen: In compliance with your request, as to keeping a record of the performance of the Olds-Close Multi-Cylinder Mine Hoist, installed for the company, and the amount of fuel consumed, I am below tabulating the work of the hoist and the fuel consumed for a seven day period:

Number of loads up.	Empty	Fuel used each day.
6	7	½ Gal.
11	10	⅞ "
7	7	9/16 "
6	11	⅝ "
7	6	½ "
7	11	⅝ "
8	9	⅝ "

Distance 170 feet.

I have been very careful in giving you the most correct measurement, but think the amount of fuel consumption will be less as soon as we get skips put in, which have been ordered. I then will give you another measurement if you so desire.

I am pleased to say that the hoist is giving entire satisfaction to the company, both for work and for fuel consumption, and it is a pleasure to run it. Yours very truly,

SAM J. BAKER, Hoisting Engineer.
C o COPPER REEF CONS. MINES, San Carlos, Arizona.

A Revolution in Mine Hoisting.—This hoist was designed by a mining engineer. It is different from the ordinary single-cylinder hoists. It has the flexibility of steam—It lifts different loads at different speeds—It starts in 10 seconds and the engine can be shut down between lifts.

Fuel economy wonderful—see letter—less than one gallon per shift.

Can be knocked down for transportation on muleback—It runs smoothly—Does not jerk; is clean, compact and convenient. Is perfectly safe—Has two self-clearing adjustable brakes.

AN ACHIEVEMENT

Improved Wood Rock Drills

They are of Vanadium Tungsten Iron.

Like all other rock drills are *now*—their chief parts *used to be* of ordinary cast iron, and even so they did better work than any other.

But now, with this remarkable metal, they give *twice the wear, do more work,* and are more easily operated than any other.

After months of experimenting and investigation, this remarkable improvement in Rock Drills is now offered for the first time to users of rock drills.

The difference between them and every single other drill is nothing short of marvelous; they cost the least little bit more, but they will save in a month far more than the difference in repairs.

It is due to your pocket to *try* one only.

Write us now. Agencies in Principal Cities.

The Rock Drill that can be "cleaned up with a sledge hammer," and "wiped off with a scoop shovel," and yet "stay with you."

Wood Drill Works

30 Dale Avenue, Paterson, N. J.

Tonnage Costs

The true unit of comparison, when deciding on the type and make of conveyor belts for your plant, is the cost of the belt per ton of material handled.

First cost is a matter of secondary consideration—in fact it bears little relation to the ultimate factor—tonnage cost.

Belts that break down quickly cause frequent shutdowns, hence loss of output, which means, in big plants, actual loss in their operation.

We have a belt for every purpose. What are your conditions? Our recommendation is based on experience covering every phase of conveyor work.

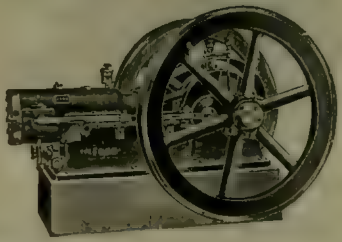
FOOS GAS, OIL AND GASOLINE ENGINES



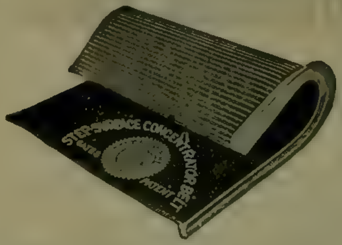
Fuel economy depends so much upon the heat and regularity of the spark that the Foos Patented, Wipe Spark Self-cleaning Igniter ultimately makes it the lowest cost engine on the market, even without such exclusively characteristic advantages as :—

The Foos System of Centerline Disc Counterbalance,
Vertical, Positively Operated Poppet Valves,
Accessibility of Oil Cups and Governor,
Speed Regulation While Running,
Pillow Blocks Inclined 45 Degrees.

Many other features are fully described in Catalog P-52 describing the Foos Horizontal in sizes 3 to 90 H. P.

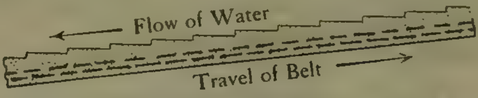
THE FOOS GAS ENGINE CO.
SPRINGFIELD, OHIO

GATES IMPROVED



Step Concentrator Belt

The surface of the Gates Improved Step Concentrator Belt is composed of a series of transverse steps, with 'treads' ¼ in. wide and 'risers' 1/32 in. high. When the belt is running on a concentrator, the 'treads' are horizontal.



Full-sized Section

This design prevents the heavy particles of mineral from escaping down the belt by holding them on each step, until dense enough to discharge the sands, when, due to the combined motion of the machine and flow of water, they gradually travel toward the mineral-discharge end of the machine.

With this belt it is almost impossible to overload a concentrator, because even if a few steps are overloaded, the lower part of the belt holds the minerals until separated The efficiency of a machine equipped with this belt is therefore greatly increased, and produces cleaner concentrates.

Our patent edge is used on the Gates Improved Step Concentrator Belt. The edge will stand up in passing around drum, and will not crack.

DID YOU EVER SEE A

Pierce Amalgamator at Work?

L. S. PIERCE
1738 Broadway
DENVER,
COLO.
U. S. A.

If you had there would be no doubt in your mind as to *why* the 'flour' gold was saved. No chance for it to float off when it is *thrown* against the amalgamated plates so often.

CATALOGUE NO. 10.

"K&J" CARS

ARE BUILT FOR "CONTINUOUS SERVICE"

Type No. 598—"Hopper Car"

Over all dimensions: Length over coupler, 12 ft. 4 in. width 6 ft. 3 in; height above rail, 5 ft. 1 in.; drawbar height, 19 in. gauge track 36 in.

Mere Strength in Cars doesn't always mean Low Maintenance Cost—

But adequate strength intelligently distributed always does.

Every lot of "K&J" Cars is intelligently built to do specific work cheaply.

MINING LAW

FOR THE

Prospector, Miner, and Engineer

By H. W. MacFARREN

356 PAGES INDEXED ILLUSTRATED $2 POSTPAID

THE AUTHOR'S purpose is to give a simple and easily grasped, though comprehensive idea of the mining law, showing its fabric and structure, that the reader and student may obtain the basic principles and facts upon which to take up either the more advanced study of mining law or use it intelligently and satisfactorily as a prospector, surveyor, claim owner or property manager. It represents the experience and observation of the writer in the mining profession, and as a mineral examiner of the Field Service of the General Land Office, in which capacity he has been in daily contact in both office and field, with miners and mineral claimants, and the subject of mining rights and titles.

This work has been prepared for the miner by a miner—using the word miner as a generic term to include all who may be interested in the subject of mineral rights and titles in contradistinction to mining attorneys—though it is believed that the work will not be without elementary interest and value to the legal profession.

CONTENTS: Origin of American Mining Law. Public Land and Its Survey. Where Locations May Be Made. Who May Make Locations. Lode Location—Discovery, Discovery Work, Location Notice, Laying Out and Staking, Changing Boundaries, Amended Location, Relocation, Annual Labor, Resumption of Work, Forfeiture, Abandonment. Millsite Location. Placer Location. Lodes Within Placers. Tunnel Site Location. Patent. Lode Patent--Survey, Application and Entry. Patent—Placer, Known Lodes Within Placers, Millsites. Adverse Claim. Protest Patent Work. Apex or Extralateral Rights. Coal Land. Timber and Stone Act. Use of Timber on Public Land. Timber and Mines Within National Forests. Water Appropriation. Digest of State Statutes Relative to Mineral Locations. United States Statutes and Regulations of the General Land Office, Approved March 29, 1909. Manual of Instructions for the Survey of Mineral Lands of the United States.

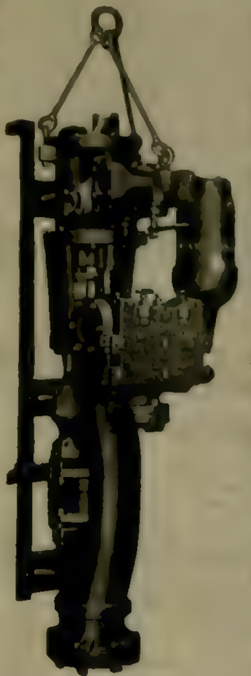
THE SLOGAN OF THE CAMERON: "CHARACTER: THE GRANDEST THING."

CAMERON



Vertical Plunger Sinking Pumps

Are Plain Work-A-Day Machines

You won't find one unnecessary part in Cameron Vertical Plunger Sinking Pumps. They are built just as strong and simple as possible, to be prepared for the hardest kind of service.

The steam mechanism consists of four stout pieces only, and there is no outside valve gear.

A Cameron Pump competes only on a quality basis with other pumps. Yet you'll find a Cameron still giving efficient service after several "cheap" pumps have gone to pieces, proving that in **ultimate** economy Cameron Pumps also come out first.

"We have had fifteen years experience with your pumps and will accept no others for shaft sinking purposes," writes the superintendent of the Teziutlan Copper Co., Aire Libre, Puebla, Mexico.

A trial will make you a satisfied user.

Write for the Cameron Catalog No. 18. It illustrates and describes all types of Cameron Pumps and is sent on request to interested pump users and intending purchasers.

VULCAN AERIAL TRAMWAYS

SAN FRANCISCO, CAL.,
June 12th, 1909.
VULCAN IRON WORKS,

Gentlemen: Tramway has been in successful operation ever since installation, and has proven entirely satisfactory in every respect. We have handled as much as 140 tons of ore on one shift. One man operates the Tramway and loads the buckets, and the buckets dump automatically in bin at other end of Tramway.

Yours respectfully,
H. MALLOCH, President,
South Eureka Mining Co.

Merrell Pipe Threading and Cutting Machinery

It is not difficult to find a machine to thread pipe. The trouble is to pick a machine that will thread pipe satisfactorily, in the most *economical* manner. There is as much difference in pipe threading machinery as there is in any kind of machinery. It's no easy task to choose the right make. To aid matters we ship our

Merrell Pipe Threading and Cutting Machines

anywhere for a thorough try-out in your own plant. If the Merrell makes good, keep it; if not, return it at our expense.

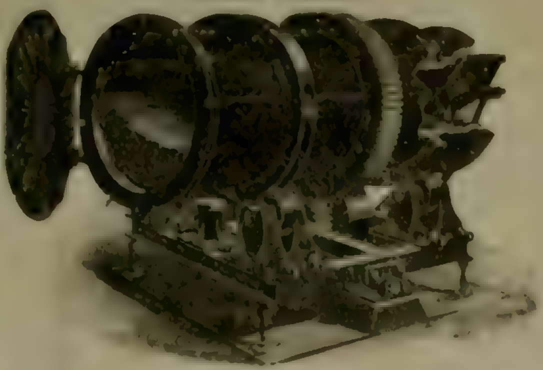
THE MARATHON MILL

(Patents Pending)



The Johnson Marathon Grinder is a multiple roll grinding mill, or tube mill with steel rods instead of flint pebbles doing two to four times the work of others, with less horse power attention and wear and tear. Equally superior as either a wet or dry grinder. As an amalgamator it beats stamps or any other mill. No flouring of quicksilver. See amalgamating channel at discharge end. High center discharge prevents any loss of values. Takes feed direct from rock breaker and produces finished product any size coarse to 200 mesh, according to adjustment, first time through without any screens, a strong statement, but the **Marathon** "makes good."

Send for results data and catalogue telling **Why** and **How** it does it.

POSITIONS WANTED

The cost of advertising for positions wanted is 2 cents per word per insertion. Minimum order 50 cents. Replies forwarded without extra charge. Remittance must accompany order.

CENTRAL OR SOUTH AMERICAN POSITION WANTED by experienced millman or assayer; references; age 28; salary reasonable. Address Box 794, this office.

DESIRE NEW ENGAGEMENT AFTER AUGUST 1ST—Technically trained engineer and metallurgist of 10 years experience in mining and cyanide branches, principally in largest camps in Mexico; perfect knowledge of Spanish language and customs; labor and revolutions offer no obstacle; specialty: satisfactory management, reliability, diplomacy, economy, system and accuracy applied in all methods; very best of reasons for change: references A No. 1. Address Box 795, this office.

AN EXPERT CORPORATION ACCOUNTANT is open for engagement; competent to devise and install systems, handle factory costs and assume full charge of an office; knowledge of mine accounts. Address Box 797, this office.

MINING ENGINEER, with 15 years' practical experience as superintendent, assaying, mining, milling, surveying, etc.; speak, write and read Spanish; accustomed to handle large mining properties and pay good dividends; best of references. Address Box 796, this office.

POSITION AS MINE OR TUNNEL FOREMAN—Understands thoroughly all branches of underground work; can work with speed and economy; foreman in Arizona, California, Nevada and Mexico; assayer; speak some Spanish; thirty years old, sober, a hustler; references; write me your proposition. Address Box 793, this office.

POSITION desired by assayer; several years milling experience, mine surveying; good mechanic, wood or iron; steam and gasoline engineering; best of references; have assay outfit; married man, 34 years of age. Address Box 792, this office.

TECHNICAL GRADUATE, with six years' experience in mining, milling, concentrating, assaying, surveying, lixiviating sliming and cyaniding, three years in treatment of refractory ores, would accept position in any of the above lines; speaks Spanish and can handle Mexican labor; will go anywhere; A1 references. Address Box 788, this office.

MINE MANAGER, 13 years' experience, expert in cyanidation and concentration, desires executive position with legitimate concern; fully qualified to handle property of any magnitude, but would take hold of good young mine, or old mine with a difficult metallurgical problem; speaks Spanish; highest references. Address Box 787, this office.

MANAGER (Bonded)—Mining engineer, with business training; experienced in assaying, surveying, general mining, milling, and cyaniding. Address Box 781, this office.

MINE MANAGER or superintendent open for engagement; technically educated; 12 years' experience as engineer, metallurgist, manager; mill design and construction of all kinds; eight years in Mexico and Spanish America; speak Spanish fluently; past three years general manager property in Mexico; A-1 references. Address 727, this office.

POSITIONS VACANT

The cost of advertising for positions vacant is 2 cents per word per insertion. Minimum order 50 cents. Replies forwarded without extra charge. Remittance must accompany order.

WANTED—First class assayer who understands bookkeeping and stenographic work. Address Box 786, this office.

WANTED—First class assayer who is competent and familiar with developing and promoting mines. Address Box 785, this office.

ASSAY OFFICE FOR SALE.

One of the best equipped assay offices in California.. A growing business in a large city; fine chance for young mining engineer with means. Price $4,000.00.

Address Box 791, this office.

Confederation Life Bdg. **Toronto, Canada.**

NOTICES OF RECENT PATENTS

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press United States and Foreign Patent Agency, the following are worthy of special mention:

PUMPING SYSTEM.—No. 994,335; June 6, 1911. Elijah H. Perkins. It is the object of this invention to provide means for removing water or other liquids from two or more wells with a single pump.

VALVE GUARD.—No. 994,409; June 6, 1911. John J. Kelly. This valve-guard is adapted to be placed over a stop-cock or the like in such manner as to prevent the stop-cock being operated or tampered with by unauthorized persons, and is especially applicable for use on shut-off valves usually interposed in water and gas service pipes near where the latter are cut in on the mains, or adjacent to the meters wherever the latter are employed.

CURTAIN MATTRESS FOR RIVER WORK.—No. 994,999; June 13, 1911. Lou G. Hare. The object of this invention is to provide a protecting mattress or revetment to be used on river improvement work in conjunction with jetties, etc., for the purpose of diverting the current of the stream or protecting the bank.

DEEP WELL PUMP.—No. 995,248; June 18, 1911. Peter J. Gildea. This pump is automatic and has a large capacity and high degree of efficiency, and by it large volumes of water, etc., can be raised from a considerable depth by the combined use of compressed air and vacuum.

VOTING MACHINE.—No. 995,093; June 13, 1911. John V. Prior. This is especially adapted to be used in lodge rooms where an expensive voting machine would be inappropriate and inconvenient; whereby the voting mechanism and the keys to operate same are entirely concealed, so that the voter may record his vote without being observed by on-lookers.

SECOND HAND MILL MACHINERY AT DeLAMAR, NEV.

We are dismantling the Bamberger DeLamar Mill and have the following items of machinery at DeLamar ready for early delivery:

6—4 ft Janey Special Chilian Mills
6—6 ft Trent Monadnock Chilian Mills
2—10x16 Blake Crushers 16—100-ton leaching tanks
2—16x30 Blake Crushers. 4—200-ton slime tanks
1—6-D Gates Crusher 40— 50-ton slime tanks
8—John Johnson filter presses
1—Trent 75 H P geared hoisting engine, motor driven
1—60 H P Stearns-Rogers friction hoisting engine, motor driven
2—5-ton Electric Locomotives, 24-inch gauge
1—60 K W. 500-volt Generator
3—100 H P General Electric, 3 phase, 60 cycle, 440 v motors.
3— 75 H P General Electric, 3 phase, 60 cycle, 440 v motors
2— 35 H P General Electric, 3 phase, 60 cycle, 440 v motors.
2— 30 H P General Electric, 3 phase, 60 cycle, 440 v. motors.
1— 25 H P General Electric, 3 phase, 60 cycle, 440 v. motor
8— 15 H.P. General Electric, 3 phase, 60 cycle, 440 v motors.
5— 5 H.P. General Electric, 3 phase, 60 cycle, 440 v. motors.

DENVER STOCK.

In our Denver stock we have a complete line of milling, mining, smelting, and irrigation machinery and supplies.

Write for our prices before purchasing we guarantee to save you money on first-class machinery.

THE S. H. SUPPLY & MACHINERY CO.
1720-28 WAZEE ST., DENVER, COLORADO.

Couple Rest With Pleasure

by including the

New Orleans-New York Steamship Line

Between New Orleans and New York in the routing of your ticket East. Costs less than an all rail route and affords an interesting and delightful diversion on your trip.

RATES

First Class Rail to New Orleans and First Cabin Steamer to New York	$ 77.75
Round Trip	145.50
One way Rail, one way Steamer between New Orleans and New York	70 00
Second Class Rail and Second Cabin New Orleans to New York	65.75

Rates include meals and berth while on steamer.
Write or ask any agent for details.

A B&B Two Bucket Tramway System Saves $100 a Month at Kittanning, Pa.

The Tramway displaces a system whereby cars of clay were pushed by hand on a 30-foot trestle extending from the mine to the brick plant. The saving in cost of haulage effected by the Tramway is about four cents per ton, amounting to pretty nearly $100 a month—principally in labor.

Where the Line Crosses a Stream.

A One Man System

But one attendant is necessary for the operation of this type of tramway. He is located at the loading station and controls the Ore Gates, regulating the flow of material into the buckets, as well as the brake and power levers.

At the discharge station no attendance is required. The buckets dump, right and lock automatically.

On lines not exceeding 3000 feet in length—where from a ten to twenty-ton capacity per hour is sufficient—this B&B Two Bucket System is the most serviceable and economical to use.

Let us explain how we can adapt it to your needs,

EDITORIAL

ARIZONA has asked the Senate Committee on Territories to amend its constitution by eliminating the provision for the recall of judges, in order that statehood may be secured.

INTERNATIONAL amenities were shown at the recent dinner at the Savoy by the Iron and Steel Manufacturers Association of Great Britain to visiting American steel producers.

RECIPROCITY in a pleasing form is seen in the proclamation of the President that subjects of Sweden residing in the United States are entitled to the benefit of our copyright law, since citizens of the United States enjoy similar privileges in Sweden.

MIAMI is a recent accession to the American shares listed on the Paris Bourse, but a later report is to the effect that no more American securities will be added for the time being, as the American Telephone incident has demonstrated that the French market is not yet wide open to American stocks.

PROSPECTORS have frequently more enthusiasm than knowledge. One such recently wrote a Denver paper that he had located a strip of territory "covering about a mile that is strictly eruptive—no country-rock whatever", and added, to clinch the matter, that the ore "at the grass roots contained $2.65 gold per ton, 2 per cent silver, and 14 per cent aluminum." Why look farther for the new Leadville?

ON ANOTHER page Mr. Edward Juessen contributes an analysis and summary of the working costs at the Pittsburg-Silver Peak mine. The notable work done there is of great interest, but we wish to commend especially the action of the general manager in thus making public, for the good of the profession, the results obtained at the mine under his direction. With the growing tendency toward the formation of large corporations has come a tendency to prevent the giving out of information that has any value or significance. This is a retrogression, and we hope that Mr. Juessen's example may be followed by others who still hold to the wiser and better policy.

CARELESS writing is often responsible for misstatements. In a report written by a gentleman who signs himself 'Mining Engineer' the statement that "silver values were encountered, and no other substance of any nature found" somehow fails to carry conviction as to the valuable nature of either the find or the report. This is not helped by the further statement that there are "no base substances present." Probably the engineer intended to say that base metals were not present in sufficient amounts to interfere with the proposed treatment. It is not necessary to write an Addisonian essay in order to describe a mine, but exactness of statement is imperative in making reports if the confidence of the reader is to be secured and held.

MANY of our readers are interested in the application of the Federal corporation tax to corporations engaged in developing minerals, and on another page we present the most important sections of the regulations thereon. As is usually the case, it will be necessary to wait for the courts to construe the law before it can be thoroughly understood. An interesting effect of the working of the law is seen in the recent action by Phelps, Dodge & Co. of increasing the book value of its properties from $2,500,000 to $24,114,045, their estimated value at the time of their purchase, in order to avail themselves of the provisions of the law as to depreciation.

MORE SPEED is the modern demand. This is exemplified by the proposal to dock trans-Atlantic liners at the end of Long Island, forwarding the passengers to New York by train at the rate of a mile a minute. A Londoner has recently made the interesting statement that it is impossible to secure speed in New York, baggage and other needs of the moment being handled with provoking slowness. The observer was slightly in error in his mechanics; speed is characteristic of American life; what is difficult to secure is acceleration, the second derivative with respect to time. The point he wishes to make in comparing New York and London in this regard hinges upon the relative cost of labor in the two cities. Personal attention can be more quickly secured in London, for life in America has somewhat the nature of a huge machine, fast-running but not easily accelerated.

PROMISES of mining development have lately characterized the movements for reform in China. The Prince Regent has urged upon Prince Pu Lun, President of the Board of Agriculture, Industry, and Commerce, the necessity for the development of the mineral resources of the empire. The immense mineral wealth of China is, next to her agriculture, her greatest natural resource. For instance, in the province of Hunan there is a series of coal beds stretching north and south for two hundred miles and east and west for sixty miles, associated with extensive deposits of iron. Shansi contains enough coal to supply the world's needs for two thousand years to come, as yet almost undeveloped. The province of Yunnan is the second in importance of the tin producing districts of the world. Up to this time mining has been entirely by native methods, but recently modern ore-dressing and smelting machinery is being introduced and will soon be at work. Modern methods will probably double the output of the mines at once, and improve the quality of the product.

THERE is an evident growing conviction that the so-called campaign of 'trust busting' has not reopened any of the avenues of opportunity, and a coincident evident growing demand for some effective deterrent punishment. The evidence is not more manifested by the attitude of the general public and the continued depressed condition of general business, than in the utterances of some of the best known representatives of large interests. Following the lead of Mr. E. H. Gary, who recently advocated Government control of the large corporations, Mr. Daniel Guggenheim, in a recent interview discussing prevailing conditions in the metal market, suggests the formation of a Government commission with power to permit or prohibit combinations in handling various products, according to the conditions prevailing. It is undoubtedly true that the more far-seeing representatives of large interests are anxious to regain general confidence. Time was, when the captains of industry felt their greatness; now, they are wearying of being classed as malefactors. The principal result for the time being is a waiting attitude, and, so far as security markets are concerned, continued dullness.

COLORADO, some time since, re-created its State Geological Survey, under the direction of Mr. R. D. George, professor of geology at the State University, and good work has been done. The legislature has voted an appropriation of $15,000 a year for the next two years for the carrying on of the work. By a recent decision of the attorney-general this becomes available at once, and in conjunction with the United States Geological Survey some excellent work on the study of the mineral wealth of Colorado can be expected. This is as it should be, but turning to California we see the other side of the picture. No appointment has yet been made to the office of State Mineralogist by the Governor and the best interests of the State suffer while the matter remains unsettled. There is no lack of properly qualified candidates; selecting the best should not require months of deliberation. Let us have action.

Concrete in Mining

Criticising a critic somewhat savors of painting the lily, yet it seems desirable to add further comment to that which Mr. Jerome B. Landfield makes on mixing concrete. Providing a skilled workman with superior tools will permit his doing better work, but providing unskilled labor with better tools than their needs require frequently produces worse rather than better results. Using an arbitrary proportion for concrete will ensure that a sufficient proportion of cement is used. To employ the experimental method suggested by Mr. Landfield both requires an expenditure of time and effort greater than is justified except for large jobs, and, unless the superintendent be unusually apt at experimental work, is extremely likely to give results that are seriously in error. To determine the voids in a given mass of sand by filling them with water appears at first sight a simple operation, but, as is well known, is actually one that presents much difficulty in the obtaining of accurate results. Furthermore, having found the amount of voids, it is practically necessary to use more cement than the theoretical amount, the added quantity being a matter of judgment, so that the operation recommended is almost the reverse of estimating in a fire-assay that one assay-ton of a flux is required, and then weighing it out within a tenth of a gram. In large pieces of work it will, of course, be both advisable and economical to determine the proportions more accurately than is worth while in ordinary work. The greatest economy in any large undertaking can be secured by grading the aggregate. The function of the cement and sand is to fill the voids in the broken rock and act as a binder. If, instead of using rock all of one size, a carefully-graded mixture of sizes is used so that the small pieces fill the spaces between the larger, the amount of cement and sand necessary can be materially decreased.

It is best, of course, not to use an excess of water in mixing, but the amount necessary varies according to the requirements of the work. In reinforced concrete work, for example, it is common good practice to use concrete much wetter than would otherwise be required, in order that it may flow freely around the reinforcing. The chief disadvantage attaching to the use of concrete for mine construction, aside from cost, is the unalterability of the resulting structure. Superintendents who have been obliged to make a hole through a ten-inch concrete wall for a steam, water, or air pipe can testify vigorously as to this. An outhouse made from two-by-fours and galvanized-iron roofing that have been utilized in several previous structures, is the best testimonial to the usefulness of these materials. Concrete has many great advantages, but it can not be used for everything, nor in every case. It needs no great commendation, for the rapidity with which its use is growing assures that it will receive proper consideration.

A National University

The now denied rumor that Mrs. E. H. Harriman was considering the founding of a new university which should excel all others in enrolment and endowment, gives rise to the question whether there exists a need for one. A privately endowed university is likely to be regarded by the donor as privately owned, and it may well be questioned whether it would not be better to increase the effectiveness of those universities now in existence rather than to increase their number. Washington, D. C., is the only city in America that has any real need of a great university, and a university there should be national in character. James Smithson's gift suggests an analogy that might well be followed, and the gift to the Nation of a site and the buildings and equipment for a great National University would be an enviable memorial. One marked deficiency in our foreign relations has been the lack of men with any adequate training for the work; ambassadors, ministers, and consuls are chosen haphazard, often with haphazard results. A step toward improvement has been introduced in the system of student interpreters, by which young college graduates are at least taught to speak the language of the country in which they are afterward expected to serve. But this is a mere learning of the alphabet; in our public service, both abroad and at home, we need a large body of men trained in the principles of government and familiar with the larger features of national life. The United States in its foreign relations has too long been in the position of the wealthy farmer who drives to town in his overalls and hickory shirt, disregarding appearances in the knowledge of his solid financial standing. It is high time that Uncle Sam put on a white collar and necktie. It is an economic waste to allow the educational influences and facilities of a great centre of government to go unutilized, and the national feeling on the conservation of our natural resources might well exhibit itself in the demand for a National University to bear to the Federal Government in some degree the same measure of usefulness that the University of Wisconsin has borne to that State.

Selling Prospects

Recent editorials of ours relative to the money available for investment in mining, have attracted much attention, and our incoming mail has increased amazingly. Apparently a large number of our readers have prospects for sale. The trouble is just that; the properties are but prospects and have not been developed sufficiently to prove what value they may possess. It is not for us to disparage a good prospect; without such there would never be mines. When engaged in the active work of the profession we put money into more than one good prospect that subsequently belied its indications, but we have no regrets. Every mining man may properly be expected to spend his quota in developing the basis of the industry. Prospects, however, are not salable; at least in the sense that they can be appraised, bought, and sold on their merits alone, as can mines. The amount involved is usually too small to stand the expense of examination by an experienced engineer, and large investors can not afford to rely on the advice of any other. Furthermore, until there is at least some ore blocked out, it is rare that sufficient work has been done to permit any exact estimate of the value of the property. There are exceptions. The fortunate circumstance that an unusually capable engineer visited the property when preliminary work had developed unusually significant indications, warranted the payment of a considerable sum for what became the Commonwealth mine in Arizona, while it was still a prospect. No one, however, could afford to pay this particular engineer his usual fees and keep him busy examining prospects. Until something definite is developed, investment must be made on the faith of the man on the ground. Without raising any question whatever as to either the competence or honesty of the prospector, it is evident that this is not a sufficient basis upon which a stranger may properly invest money in what is admittedly a long chance. Individual effort and small partnerships based on personal acquaintance, must be the main reliance in converting prospects into mines. Until that stage of development has been reached, any effort to interest strangers is not likely to be successful. Occasionally when the investor or his engineer can, with nominal expense, inspect a prospect, it is possible to interest outside capital, but such instances are rare.

There is another and an important phase of the matter. A prospector almost invariably overestimates the extent of his knowledge of the property. He sees favorable indications everywhere. If he did not, he would not continue to prospect. How serious this may be is instanced by the experience of one engineer sent to examine a pile of tailing represented, in good faith, as amounting to 300,000 tons. It took but a few minutes on the ground for the engineer to convince the optimistic owner that the actual tonnage could not possibly be much more than one-tenth of the amount claimed. The man simply knew nothing about the methods of estimating such materials. In another case a prospect was represented as showing "a thousand tons" of ore of a certain value "in sight". Questioning the owner developed the fact that the deepest hole on the vein was twenty feet, that there were no cross-cuts, levels, or winzes, and nothing in fact but the outcrop and a few assessment holes. It is possible that more than a thousand tons may sometime be mined from this property. We sincerely hope this may prove true, but it is evident that there was no ore 'in sight'. The method followed in determining the value of the ore was equally accurate. The owner had "broken off pieces along the outcrop" to the total amount of fifteen pounds, and had the material quartered and assayed. He was honest in his belief that he had not selected the best ore, though any experienced sampler, remembering the hypnotic influence a valuable mineral exerts over a prospector's pick, might well reserve a doubt. The disproportion between a 15-pound sample and a 1000-ton block of ore, had not appealed at all to him. In still another case a bright and earnest young man wanted some stranger to join him by putting in two or three thousand dollars to drive along a vein to find a possible ore-shoot not discovered when cross-cut by an adit, and lost at forty feet in sinking from the surface. Questioning in this case revealed the fact that it was by no means certain that the 40-foot shaft had not been sunk in a landslide. In that event the search for the parent ore-shoot might well be long and costly. In any event, expert knowledge of a peculiar type was evidently needed as much as money.

These cases have been cited, not in levity, but to illustrate the very real difficulties that lie in the way of developing and selling prospects. In each instance the owner impressed us as honest, as having more than usual ability, and the properties as having some probable merit. But these are not, in our judgment, good investments on the basis of the facts as the prospector was able to present them. Until prospectors learn much that they do not now know about sampling and measuring ore, and until they have more knowledge of economic geology, they are likely, we fear, to have to continue to depend upon personal friends for funds supplementary to their own. A few mining men, wearied in the search for mines, occasionally pay roundly for a prospect, but this is the exception rather than the rule.

Cost of Mining at Silver Peak

By Edmund Juessen

The mines of the Pittsburg-Silver Peak Gold Mining Co. are situated on the slopes of Mineral ridge, a spur of the Silver Peak mountains, three miles distant from and 2000 ft. above the company's mill and cyanide plant at Blair, Nevada. They comprise a number of properties on a 'gold quartz' bearing zone of metamorphic schist, forming the basal member of a series of sedimentaries, and resting on an intrusive mass of granite.

Some of these properties were first worked forty years ago, the ores being treated in small stamp-mills at Silver Peak, requiring a wagon haul of over seven miles. These early operations were restricted to 'rich streaks' of the outcropping ores, the handling en masse of the large low-grade orebodies, of which they were part, being undertaken by the Pittsburg-Silver Peak Gold Mining Co. after consolidating the properties and providing for the transportation facilities required for their joint and economical operation.

The profitable handling of the low-grade ores, occurring in flat-dipping, lens-shaped bodies intercalated in schist, required a method of development and mining which would reduce the elements of cost, such as 'dead work,' handling of ore in stopes, supporting underground excavations, and transportation in general, to the minimum obtainable under the existing high-labor scale of the district. The firm hanging wall of the individual lenses, and the further fact that an appreciable extent of the ore zone had been partly bared through erosion of its overburden, favored economical extraction under otherwise trying conditions; permitting the use of pillars in place of timbers or filling for the support of the underground excavations and making possible the employment of the glory-hole and open-cut methods of mining in the extraction of from 35 to 40% of the total ore tonnage.

The following details of mining and development expense for the month of December 1910, are illustrative of the mine performance since the beginning of 1910, when certain changes were made in the underground methods, bringing about a reduction in the cost of handling the material in the stopes and providing the facilities for winning a large percentage of the ores remaining in the pillars supporting the excavations.

The costs of underground and glory-hole mining and the incidental development have not been segregated in these statements. They vary slightly from month to month, in keeping with the relative percentage of tonnage gained from the different workings. At present the underground ore represents 60% of the total tonnage and 73% of the total cost, while glory-hole and open-cut mining produces 40% of the ore at 27% of the total cost.

The ore won through glory-hole and open-cut mining is considerably lower in grade than that coming from underground workings. This is partly due to a more scattered condition of lens occurrence near the surface; partly to a cutting down of the ore values through an admixture of waste in mining, unavoidable in carrying on glory-hole operations in a flat-lying orebody having an overburden of barren material.

The ability to vary the proportion of underground and glory-hole ore in keeping with any material fluctuation in value and cost of production has been provided for through extensive development of the property. These figures include a *pro rata* portion of the general expense and in addition a charge for *Suspense Account*, in which all expenditures are carried that are made for betterments, reconstruction, and large items of equipment necessary to maintain the plant at full work-

A Commenced work on flat raise
B Completed flat raise haulage system
C Commenced glory-hole mining
D Changed underground mining methods

ing efficiency. Depreciation of plant is not considered under operating costs, being cared for through an annual 'writing off' from profits of an amount commensurate with the estimated lifetime of the property. As is the case in all enterprises of this character, the initial costs of operation at Silver Peak were materially higher than those shown in the preceding statement, economies being effected gradually, as the knowledge of conditions to be met grew and the methods of work were perfected. This is shown by the following analyses of costs, including in its scope the mine performance from the beginning of the year 1908 to the close of the March quarter, 1911. To emphasize the gradual increase in efficiency of labor resulting through improved methods of work, the charges for miners, muckers, and trammers appear separately from other labor.

The flat raise haulage system is 1400 ft. in length, and connects all of the operating levels of the property. Its driving cost was charged off to *Development*, its equipment to *Mine Equipment* account, as the *Suspense Account* now in use was not in effect at that time. This accounts for the fact that the development costs during the period December 1908 to September 1909 were materially higher than during the other operating periods of the property.

It is manifest from an inspection of the cost figures for the period March 1908 to March 1909, that the Silver Peak mines, at that time, were no exception to the rule that "the producing power of a mine is always overtaxed through a heavy tonnage demand before the handling methods have been sufficiently advanced to permit of economical extraction."

The average efficiency per shift of mine labor can be calculated from the following division of labor for the month of December 1910, and the mine perfomance during the same period of time:

Mine Labor.	Shifts.
Shift bosses	62
Machine men	531
Machine men helpers	167
Shovelers	529
Timbermen	16
Timbermen helpers	16
Trammers	145
Shovel crew	84
Shovel train crew	29
Hoist men; pipe men	243
Total shifts	1822
Other Labor.	**Shifts.**
Supervision	155
Shop	217
Electricians	122
Carpenter	31
Yard	124

During this month 13,061 cars of ore and 2187 cars of waste were handled; the ore tonnage amounting to 15,668. Expressed in terms of tons of product per mine-labor shift, considering only the ore tonnage, the performance per man equals 8.6 tons per shift of eight hours.

The wage-scale paid will be of interest in comparing the labor efficiency secured at the Silver Peak mines with the performance at other mines, operating on low-grade ores, occurring under similar mining conditions.

WAGE SCALE

(Per shift of 8 hours.)

Shift bosses, carpenters, machinists, electric workers, shovelmen	$6.00
Locomotive engineers, blacksmiths	5.50
Hoist and compressor engineers, motormen, tramway brakemen, linemen	5.00
Machine men, timbermen, skipmen, crushermen, shovel helpers, machine men helpers	4.50
Muckers, trammers, blacksmith helpers, yardmen, and all other labor	4.00

The complete costs of mining, crushing, aerial tramming, and milling for December 1910 are given in the table below. As in the figures for mining and development discussed, the other items of this statement contain a charge for *General Expense* and *Suspense Account*. It will be observed that all items of cost other than aerial tramming are in harmony with the low cost of mining. The excessive tramming cost for December 1910, as well as for the month of November of the same year and December 1909, are due to an almost complete reconstruction of the tramway line, which is 12,800 feet in length. This was necessary in order to increase its handling power in keeping with the increased mine tonnage.

Concrete in Mining

By Jerome B. Landfield

No engineer is today inclined to doubt the large part that cement is destined to play in the future of mining and milling operations. Already mine managers have had much to do with concrete in the building of foundations, retaining walls, sluices, and the like, and successful experiments have been made in adapting it to supersede mine timbers under certain conditions. But the employment of concrete in mining is still in its infancy, and practical methods in the use of cement are not as familiar to mining engineers as they should be. Mr. Del Mar's article on concrete in the *Mining and Scientific Press* of April 15 contained much interesting and valuable information, but there was also much in it that savored of the handy reference book, and in certain details it should be revised.

In the first place, no mine or mill superintendent, in mixing concrete for any important use, can afford to go by the rule-of-thumb method of proportioning his aggregate. To lay down a rule that the mixture should be 1 : 2.5 : 4.6, or any other arbitrary proportion, is to ignore absolutely the differences in materials in different places. There is, on the other hand, a simple method of determining the proper proportions of any materials selected. Two things only must be borne in mind. The first is that the cement is just what its name implies—it is the binding element. By itself it is neither as strong nor as durable as in combination. It is a common error to believe that concrete is necessarily made stronger by increasing the proportion of cement. The other thing to remember is that the best proportioning of the aggregate is that which leaves the smallest amount of voids. This is a comparatively simple matter to ascertain, and differs materially according to the character of the sand, gravel, and rock used. To determine it, first take a given amount of the gravel, or broken stone, and place it in a bucket the contents of which are known. Having calculated the number of cubic inches in the bucketful of gravel or broken stone, fill it with water. The amount of water required to fill it will show you the voids that must be filled with sand and cement. A similar test of the sand will give you the proportion of cement to sand.

It is a mistake to suppose that an excess of water in mixing concrete will do no harm. The right amount of water should be used—no more and no less. This differs under various conditions. If concrete is placed in mass in practically watertight molds, the amount of water used may be increased considerably without harm, but there must not be enough to have a tendency to flush neat cement to the surface, or to cause a sizing of the aggregate.

On the other hand, where a large surface is to be covered with a comparatively thin layer of concrete, much less water should be used. In floors and the like, one surface is subjected to absorptive action, while the other is at the mercy of atmospheric influences. Here the danger is that if water drains off it will carry with it particles of cement, and if it flushes to the top it will delay finishing, so that the trowel will disturb elements that have begun to get their initial set. In general, a floor that has been laid with concrete mixed too wet will dust off badly. The correct method is to mix coarser concrete so that it will tamp without quaking, and finer concrete for a top coat so that it may be molded in the hand. To secure a hard and durable finish, tamp this latter material so that just enough moisture comes to the surface for finishing immediately. Then be careful not to trowel it too much. It then should be protected against atmospheric influences and the best method is to cover it with damp sand as soon as it has taken its initial set.

There is a little trick known to practical concrete men that may interest mining men, and that is the way in which fresh concrete is made to bond to old. This is especially important where concrete work has to be done by stages, or where repairs have to be made. The old surface is, of course, first carefully cleaned, preferably with a wire brush and plenty of water. Then it is painted over with a grouting of neat cement mixed to the consistence of batter. If the fresh concrete is then promptly put on, there will be no difficulty in making a good bond.

One of the most important problems that have engaged the attention of concrete engineers is that of waterproofing, and it is not necessary to say that this is of particular interest to the mining man. There are in the market scores of waterproofing devices, most of them unsatisfactory for one reason or another. Most of them waterproof but temporarily, and others waterproof at the expense of strength. Nearly all waterproofing devices may be divided into integral and surface treatment. The surface treatments are many, but at the present time the most satisfactory are two. One of these is to paint the surface with some kind of gilsonite paint, and the other is to wash the surface with sodium silicate (water glass). The process is to put on the wash, let it remain for a few hours to sink in, then wash it off. The operation is repeated several times, and the result is a glazed surface.

Waterproofing agents to be mixed with the concrete are legion, and most of them are worthless. A simple method sometimes followed with success, is to add a little alum to the cement, and put some soap in the water with which the concrete is mixed. The aim of integral waterproofing is to attain density, and the most satisfactory way of attaining this density is to add to your cement a small proportion of pure hydrated lime. The most perfect method of waterproofing, however, is just now the subject of patent litigation before the United States Supreme Court. This may be termed the calcium oleate process, and consists in making a combination of lime and animal fat, pulverizing it, and then adding to it the clinker in the cement mill before this is ground. The result is a waterproof cement for all uses. The strength is not impaired, but is in fact increased, owing to the fact that the finest particles, which would naturally set too quickly, have their setting somewhat retarded.

Possibly the most interesting recent development in cement matters, from the standpoint of the mining man, has been the invention of a means of applying concrete to a surface by means of compressed air. This process, familiarly termed the 'cement gun' process, is the invention of Carl Akeley, the naturalist of the Field Columbian Museum at Chicago, and it was for renovating the façade of this building that it was first used. Some practical business men and engineers obtained the invention, and proceeded to develop its commercial possibilities. For two years laboratory experiments were carried on, and last December it was for the first time exhibited publicly, at the Cement Show in New York. The principle of the machine is to force a steady stream of dry sand and cement, previously mixed, through a hose. Another smaller hose carries water, which is injected into the mixture of sand and cement just as it is leaving the nozzle. A most remarkable result is thus attained. When the mass thus projected strikes any surface, the sand falls and a grouting of neat cement automatically forms on the surface. Then the sand commences to take hold and regular cement mortar is formed. This mortar bonds with almost any surface, brick, concrete, iron, etc., and is exceedingly dense, owing to the fact that each particle is practically shot into place under pressure. All surplus moisture is forced out, and the mortar in setting becomes very hard and will absorb only a fraction of the water absorbed by ordinary hand-made concrete.

That this machine possesses wonderful possibilities for mining men will be seen at a glance. In the first place, it is possible to build sanitary and fireproof houses and other buildings in desert and tropical regions at a very low cost. All that is necessary is to put up a light steel frame, cover this with wire mesh outside and inside, with a backing of tar paper to act as a mold, and then with the 'cement gun' put on an outside and inside layer of cement stucco. Inasmuch as one machine will put on a square yard of one-inch stucco in two minutes, it will be seen that the operation is not expensive. Old frame buildings may be made over and fireproofed in this way. An example of this I recently witnessed at Orange, N. J., where the manufacturing company took a contract to make over a large frame building into a fireproof milk depot. Much could be done underground with a machine of this character. All that is required is a comparatively inexpensive machine for use in connection with the air from the compressor, and a supply of sand and cement. A stream from the nozzle will penetrate a layer of broken stone to a depth of six to eight inches, making of it a mass of dense concrete. A quantity of waste rock simply piled up or crated in with wire netting could quickly be turned into a retaining wall or support that would last to the end of time. With the machine many clever ways of dealing with soft ground could be devised. Thus far the machine in question has only been used commercially in house building, so far as I know, and I shall await with interest experiments with it in the mining field. At any rate, it seems deserving of a little description, so that mining men, as well as those in other fields, may be prepared to take advantage of whatever possibilities it has in store.

The Tin Disease

It is a well known fact that tin exists in two allotropic modifications known as the white and gray. The white is the ordinary form, the former passing into the latter when the temperature is sufficiently low. The following is taken from a recent study by Ernest Cohen, published in *La Technique Moderne*. The first clear case of the disease occurred in a lot of Straits tin stored in a Russian custom-house during the winter of 1868. When it was time to remove it, it had fallen into powder. This was attributed to the intense cold of that winter, the phenomenon afterward being reproduced by artificial refrigeration. According to Cohen's researches, at the temperature of 64°F. there is a change from white to gray tin, which goes on with increasing velocity until a maximum is reached at −40°F., after which the velocity decreases, the change ceasing at −172°F. The first symptoms are small swellings like warts or grains, the trouble beginning at isolated places, but quickly spreading from point to point. The tin changes from white to gray, it crumbles to powder, and undergoes partial oxidation, the volume increasing somewhat. In the early stages the reaction is reversible, in the later stages it is not, and the powdered gray tin has the property of infecting good white tin. Consequently, if any objects are attacked they should be removed from the neighborhood of uninfected pieces, and it is recommended that the temperature of cases in museums which contain tin objects should not fall below 68°F. at any time.

Economic Geology of the Philippine Islands.

By Warren D. Smith

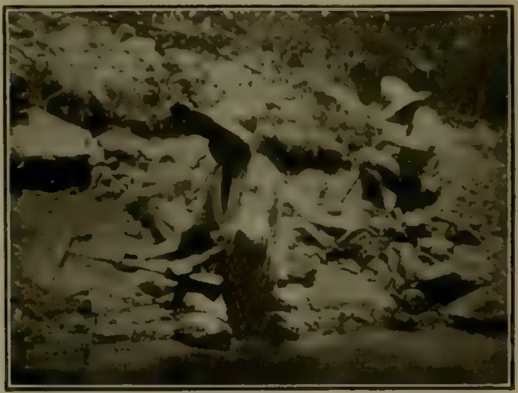
*Gold. This metal has been found in some quantity in nearly every part of the archipelago. It was mined in a crude way as long ago as there are records. I have been in ancient workings on the islands of Masbate which probably were made by Chinese years before the coming of the Spaniards. Magellan heard reports of gold in the Camarines when he reached the Islands in 1521. Although it is not the most important mineral asset of this, or, as a matter of fact, of any other country, yet gold holds the first place, for it is the easiest to mine and does not depend upon a market. The three principal districts where gold mining is now being carried on are Ambos Camarines, Benguet, and Masbate.

MAP OF THE PHILIPPINE ISLANDS.

In the first-named district, near Paracale, mining is largely confined to dredging, although vigorous development on the lodes is in progress. The country-rocks are largely schistose diorites, gneissic granite, and slaty shales. These formations are similar to those found on the islands of the Karimoun archipelago near Java. The veins, as far as we now know them, are of only moderate width, but very rich; pockets running as high as one or two thousand dollars, gold, per ton have been encountered. Some of the gold is found in the quartz filling along the contact of the diorite and granite, but several good veins are normal to this contact. Lode mining is farther advanced near Mambulao, there being 20 stamps dropping on the San Mauricio property and a Huntington mill operating on the Tumbaga. On the Paracale river there are two New Zealand dredges, while an American (Risdon) dredge is digging in the Malaguit. A large Bucyrus dredge will shortly be installed on the Gumaus river.

The dominant rocks in Benguet are diorite and andesite, and the gold is found in fairly large quartz and calcite veins in north and south, east and west, and northwest and southwest systems, cutting the formations indiscriminately; that is, they are fissure veins. Gold occurs both native and as telluride. The ore is not entirely free milling, and cyaniding is resorted to. The chief characteristics of this ore, except in one or two cases, are the general absence of manganese and the abrupt change from an all quartz gangue to all-calcite within very short distances. Altogether, there are only nine stamps dropping at the present time, two mills having been badly crippled in the fall of 1909. However, two new mills are about to begin operations.

In the mining district of Masbate the country-rock is largely andesite, in old, worn-down volcanic stocks. The andesite is cut by a system of northwest and southeast quartz veins, one of which is over 20 metres wide. The ore is oxidized to a much greater extent than is the case in Benguet, but is only partly free milling. This ore also contains large amounts of manganese oxide. There are four principal companies in this district, but not one in the producing stage at the present time. Some dredging was attempted in this district, but for various causes it was unsuccessful.



NATIVES BREAKING ROCK, SAN MAURICIO.

Other promising regions are near Cabua and in Nueva Ecija, Luzon; the Cagayan-Muniqui-Pigtao district, Mindanao; the Surigao peninsula, Mindanao; the island of Catanduanes; Pangasinan province, Luzon; and Mindoro island. The gold mined in 1909 amounted to ₱495,194.*

Silver.—Some silver is found in all the gold districts, usually alloyed with gold. Native silver has been encountered in Benguet in small quantities. Practically all the lead is argentiferous. The production in 1908 was ₱2750. That for 1909 was not estimated separately.

Copper.—Copper has been found in the form of arsenates and sulphides in the Mancayan-Suyoc district of the Mountain province, Luzon, as native copper in Masbate, the Camarines, and the island of Jolo. The best known deposit is that in the Mancayan-Suyoc district. Eveland writes as follows concerning this deposit: "In view of the fact that the entire region, with the exception of the one orebody of the Mancayan mine, is in an early stage of development, it is impracticable to treat the ore deposits in detail. It seems to be fairly conclusive, however, that the general type of vein in the district is a narrow quartz lead, carrying metallic sulphides, in some cases of copper, and generally with gold associated in a free state. These veins are in the Mancayan diorite which underlies the entire district. With the advent of the 'trachyte' flow, metamorphic changes have taken place, and the nature of the country-rock is altered to a considerable degree." Recent development work has shown this deposit to be rather in the nature of a stockwork, and it appears to me to be more extensive than was thought to be the case.

---

*Abstract from the *Philippine Journal of Science.*

*The Philippine peso = 50c. gold.

Lead and Zinc.—Lead and zinc are associated in some of the Camarines deposits. Argentiferous lead occurs in many localities, principally in Cebu and the island of Marinduque. In Cebu it is of the nature of a stockwork in an andesite flow.

Iron.—Iron ore in the form of hematite, magnetite, and limonite, with varying percentages of iron, has been found in several localities. However, there is a fairly well defined belt which follows the east coast of Luzon for a short distance, beginning in the Camarines and then swinging into the interior, where it reaches, as far as our knowledge now goes, its greatest development near the town of Angat in Bulacan province. Three small blast-furnaces of crude design are now operated by a Filipino woman.

The following is an analysis of the ore from this place:

Constituent.	Per cent.	Constituent.	Per cent.
SiO_2	2.24	CaO	0.12
Al_2O_3	6.52	K_2O, Na_2O	...
FeO	1.92	H_2O	0.04
Fe_2O_3	88.22	CO_2	0.01
MgO	0.18	TiO_2	0.77

Manganese.—Manganese oxide occurs in Ilocos Norte in nodules concentrated in shallow beds. The origin of this substance has been traced by Smith to small stringers in a recent andesite flow. Manganese occurs in small pockets in the quartz veins in the gold districts of Benguet, Masbate, and Camarines.

Coal.—Coal is found on nearly every island of the archipelago. The principal localities are Batan island, Albay province, Luzon; near Compostela and Danao, Cebu; near Cataingan, Masbate; near Bulalacao, Mindoro; near Sibuguey bay, Mindanao, and near Burdeos, Polillo. The coal measures belong to the Tertiary period. The coal is subbituminous, and an analysis (by Fox) from Batan island gives the following figures:

	Per cent.
Volatile combustible	39.98
Fixed carbon	48.80
Ash	5.70
Moisture	5.74
Sulphur	0.66

A sample from Cebu gave the following analysis (by Cox):

	Per cent.
Volatile combustible	36.44
Fixed carbon	54.48
Ash	4.12
Moisture	4.86
Sulphur	1.88

The production in 1909 was 31,000 metric tons. There is only one producing mine at present: the East Batan Coal Co. on the little island of Batan.

Petroleum.—Oil seeps have been noted at two places on the island of Cebu, two in Leyte, four on Tayabas peninsula, and one in the Cotabato valley in Mindanao. Three oil wells have been drilled, but no appreciable flow has as yet been obtained. One well in Cebu reaches a depth of 1100 feet. The oil occurs in Tertiary sandstone and shales. The oil from Tayabas gives these results:

	I.	II.
Specific gravity of filtered oil at 15.5°C.	0.845	0.831
Initial boiling point	80°C.	70°C.
	Percentage.	
First fraction, light oils 70° to 150°C.	27.0	36.5
Second fraction, burning oil 150° to 300°C.	56.75	48.75
Residuum above 300°C. by differences	16.25	14.76
Total	100.00	100.00

Phosphate.—Small deposits of guano have been found in limestone caves, but no rock phosphate. One small deposit of apatite crystals has been found in Ilocos Norte.

Sulphur.—Small deposits, scarcely large enough to be of commercial value, occur in Leyte on the island of Biliran, Mount Apó in Mindanao, and a few other scattered localities. Ferguson found a fair deposit on the island of Camiguin in the Babuyanes group.

Salt.—No large natural salt beds are yet known in the Philippines. Some very salty springs occur in several provinces, principally in the mountain province of Luzon.

Asbestos.—Asbestos of the anthophyllite and baltimorite varieties occurs in Ilocos Norte, but as yet only occasional veinlets of chrysolite have been seen. There is no production and but little development work.

Mineral Waters.—The two principal springs are at Sibul, Bulacan, and Los Baños, Laguna. During 1908, 268,440 litres were bottled and sold.

Clay.—Crude ware, *pilones*, cooking pots, brick, and tile, all burning red, and unglazed, are made throughout the islands. Some glazed ware has been manufactured, using common salt glazing, but little fine faïence has been attempted. In Laguna province some deposits of kaolin occur, but they are not extensively worked. Orthoclase feldspar and sand suitable for glass making have been found in a very few places. Good glass sand has recently been discovered in Ambos Camarines.

The Glycerine Supply

LONDON CORRESPONDENCE

Much has been heard recently of the serious rise threatened in the price of dynamite and allied explosives, owing to the enhanced cost of glycerine, which is the base of nitroglycerine manufacture. As most of the glycerine used throughout the world for this purpose is made in England, the cause for this increase in price is more readily studied here. Glycerine is a by-product in soap manufacture; when animal and vegetable oils are treated with alkali, soap and glycerine are formed. Except for its use in pharmaceutical preparations, glycerine was of no commercial value until nitro-glycerine was invented, and nowadays, owing to the restricted circle of explosive-makers, little is heard of it as an ordinary market commodity. The 'spent lye' left behind in soap manufacture contains about 9% of glycerine. The relative amount of glycerine and soap produced by the reaction varies widely, according to the nature of the raw material and the kind of soap produced. Most of the soap-makers boil the lye down to produce a crude 80% glycerine. Only a few of the large houses make a refined product; the others either sell it to the bigger firms, to the limited number of explosive manufacturers who undertake refining, Nobels being the chief, or to merchants who buy for the American demand. The British Government cordite works do not refine glycerine, but buy it mostly from Nobels. At the beginning of 1907 crude glycerine was worth £28 10s. per ton, and refined £50 per ton. By the end of the year crude had advanced to £68 and refined to £105 per ton. The cause is to be found in the advance in the price of oils and fats. The soap-maker has found it impossible, or at least injudicious, to recoup himself by increasing the price of soap, owing to its being a national commodity necessary to the poorest classes, so has had to turn his attention to the other outlet of his commodities. It is also interesting to note that the chief reason for the advance in the price of fats and oils is their increasing use in the manufacture of oleomargarine. Some of the largest soap-makers have found it necessary to protect themselves by becoming their own producers of vegetable oils. Taking all these facts into consideration, it is obvious that the fear that explosives will continue to advance in price is only too well founded. It may seem remarkable that an article of circumscribed application such as dynamite should not be able to get as much raw material as required, produced in connection with so universal a commodity as soap. Is it permissible to suggest that the proposed compulsory baths for miners will cause, by the increased use of soap, an increased supply in glycerine, with a resulting reduction in its price? In this way the mining fraternity would benefit not only in health but by a decrease in the cost of explosives.

North Washington Power & Reduction Mill

By M. H. Joseph

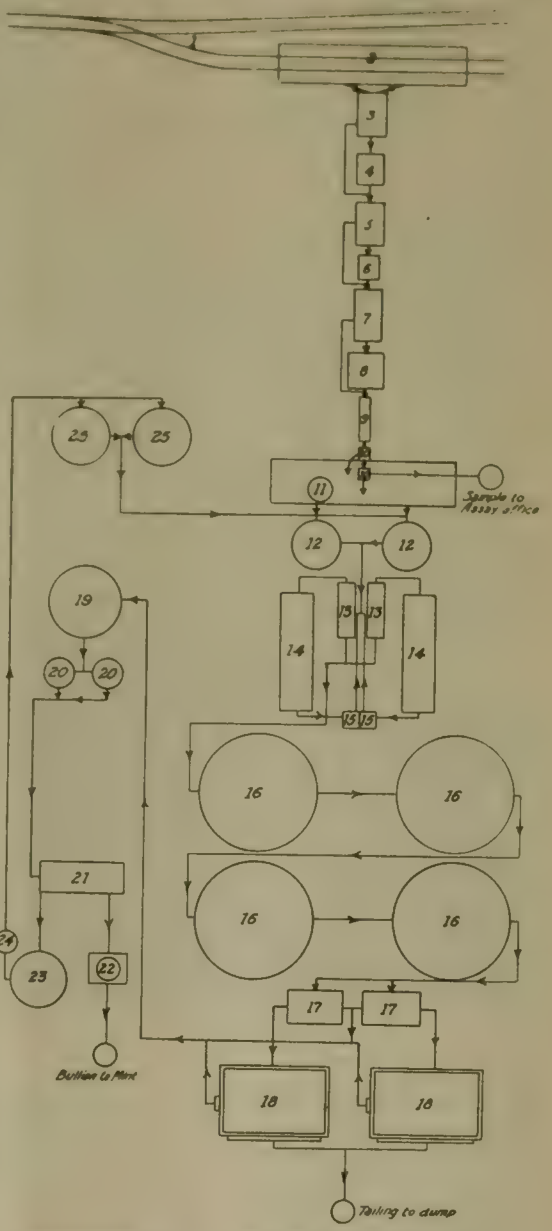
The mines at Republic have previously had but a small and precarious outlet for their ores, dependent on the demands of distant smelters for highly siliceous materials, especially for use in converter linings. Of late the smelters have used the Republic ores in fluxing the lead ores of the Coeur d'Alene and other districts, but as no ore containing less than $11 in gold and silver per ton will pay a profit over the cost of mining, transportation, and treatment at distant reduction centres, a less expensive treatment for lower grades of ore by local milling processes has become a necessity. In the milling practice formerly in vogue in Republic the mechanical limitations of fine grinding and the subsequent treatment of finely ground pulp, caused great difficulty. The gold in the ores of the camp, though mechanically free in a dense matrix, is ordinarily so finely divided as to be invisible, except by microscopic examination. Silver occurs in some of the high-grade ores in the form of selenide of silver. Native silver is occasionally found in medium-grade ore, and it occurs throughout the ore as a sub-sulphide of silver and also alloyed with gold. Various analyses and metallurgical tests have proved that the incomplete recovery of gold and silver by cyanidation at Republic is due, not to the presence of rebellious minerals, but to the density of the ore which would not permit permeation by the cyanide solution.

The new mill, designed by H. W. Newton, will treat 1000 tons of ore per day and will be constructed in eight units of 125 tons each, two of which were expected to begin operation about June 1. In addition to the main building, there will be a crushing plant, refinery, assay office, pumping station, warehouse, and business office. The machinery will be electric-driven, with power generated at the company's plant, at Similkameen Falls, near Oroville, Washington, to supply power and light for the mines and mill, and to light the town of Republic. An auxiliary plant will be included in the mill equipment, with 325 kw. of electric power available for use, in case of interruption of power along the transmission line.

A spur of the Spokane Falls & Northern railway crosses the millsite, and over it the ore will be conveyed from the mines to the storage-bins of the crusher plant, from which it will go through the following stages of treatment: From the storage-bins the ore is fed to Blake crushers by a shaking-screen, the undersize, together with the product from the crushers, falling to grizzly bars spaced to one inch. The oversize from the grizzlies is fed to Dodge crushers, and the product, joining the grizzly oversize, gravitates to trommels. In the trommels, all the material passing a ¼-in. ring is removed, the oversize passing to rolls set to crush ¼ in. The product of the rolls, with the undersize from the screens, is carried by a conveyor-belt to the mill-bins, where an automatic sampler removes a cut for assay, the reject falling to a second conveyor-belt, which automatically distributes the ore to the bins.

From the mill-bins the ore is fed by plunger feeders to Trent Chilean mills, where it is ground in cyanide solution to pass 20-mesh screens. The product of these mills flows to Akins classifiers, where all the material fine enough for cyanide treatment overflows to Trent agitators, the classified sands dropping to the feed-box of the tube-mill, where these sands are reground so that 85% will pass 200 mesh, after which they flow to the elevator sumps. From the elevator sumps bucket-elevators return the pulp to the Akins classifiers, where any remaining unfinished product is removed, the finished pulp going directly to the Trent agitators, connected in series, where the pulp is agitated, passing through the series of tanks by displacement to disc-thickeners.

In the disc-thickeners the pulp is relieved of a portion of its enriched solution, which passes to the precipitation department, the thickened pulp flowing to Oliver filters, which separate the remaining solution from the ore by vacuum filtration, the solution passing to the precipitation department, and the ore to the tailing dump. In the precipitation department the solution is mixed with the quantity of zinc-dust necessary for the precipitation of the gold and silver, and is pumped to the refinery, where the gold and silver precipitate is removed in a filter press, the barren solution again entering the mill circulation. The precipitate is periodically removed from the press, melted, and cast into bars.



FLOW-SHEET, NORTH WASHINGTON P. & R. CO. MILL.

Only about 10 per cent of the world's output of graphite is used in the manufacture of 'lead' pencils. Graphite is not fusible and is therefore employed, either pure or mixed with clay, for making crucibles for use in the steel, brass, and bronze industries. It has no equal as a lubricant, and is used extensively in electrotyping and electroplating, for it is a better conductor of electricity than most other forms of carbon. It is also a constituent of a paint used to preserve iron and steel.

Factors in Cost of Oil Production

By William R. Jewell

A question of vital importance to the oil industry of today, and one which is invariably a subject of inquiry by the prospective investor in oil property, is the cost of production. The question, 'What does it cost to produce oil?' in general cannot be answered. First of all, what does the inquirer mean? If he is a novice in the oil business, it is likely that he wishes to know what it costs to pump oil and maintain production after the wells have been completed. If he intends to purchase oil property for the purpose of development, his inquiry assumes proportions of such magnitude that it can be answered through only a detailed exposition and correlation of many factors, every one of which must be, as nearly as possible, determined before the problem can be worked out. Failure to proceed along these lines has ruined many companies, and brought keen disappointment to a multitude of stockholders, who have been led to expect magnificent dividends through the misrepresentation of the promoter; misrepresentations often due to his ignorance rather than to intention. On the other hand, accurate determination of all the factors attendant on cost of production and operation would place the oil business in the investment class rather than in that of speculation.

If all the oil produced in California up to January 1911, amounting to about 379,743,268 barrels, were balanced against the total amount of money spent in producing it, taking into account the immense cost of all the wells which produced no oil, the cost of production would be found to be many dollars per barrel. It is a fact that the great oil companies of today have produced their oil during the first five years or so of their existence at a cost of at least $5 per barrel. Data have been gathered by H. B. Guthrie showing that from 1888 to 1908, of a total of 5611 wells drilled, 1017 were failures. Thanks to the 'wild-catter', who has spent millions in drilling in unproved territory, we have our wonderful California oil fields. But while it is interesting, it would avail nothing in a practical way to determine the average cost of oil production throughout the State. It is my purpose to enumerate in this article the factors determining cost of production, deduced through a study of conditions in the various fields, and to present representative examples showing how the costs work out.

Acreage and capacity of production are of fundamental importance, for upon these depend the purchase price of the land, the number of wells that may be drilled thereon, and the maintenance of production over a long range of years. It is more economical to produce from two wells than from one, and manifestly the cost of operating on a large scale may be reduced to a minimum. Capacity for production may be approximated through a knowledge of the thickness and degree of saturation of the oil sands. This is a matter for the geologist to determine from an examination of the formations. The value of the land depends almost entirely upon capacity; but is modified by the character of the formation, depth, accessibility for supplies, fuel, and water, upon which depend the length of time and cost to drill.

The next problem to be considered is the determination of the time necessary to redeem the capital expended, for the interest accumulating upon this invested capital will be large and must be charged to cost of production. The extent of initial development in the majority of instances is restricted by the available capital. And, knowing the time required to drill a well, the cost of the well, and the cost to maintain production, the number of wells that can be simultaneously drilled may be estimated. This having been done, time of redemption of capital may be expressed in this theoretical equation:

$$X = \frac{C + c + (C + c + O) \times .1}{Y.P.p.}$$

where X = time required to redeem capital
Y = number of wells
P = selling price per barrel
p = production in barrels
C = capital invested
c = cost of wells, pumps, accessories
O = operating expenses.

Thereafter development may be carried on within the limits of the earnings of the company. As can be seen from the above equation, the purchase price of the land is an important factor in the determination of the cost of production. Many of the successful oil companies acquired land at as low a figure as $2.50 per acre; land which later was easily worth $2500 per acre. I have in mind a certain tract of land in the Kern River field which cost its present owners $2.50 per acre. Shortly thereafter, adjacent property of precisely similar character was purchased by the Claremont Oil Co. at $4500 per acre. Notwithstanding the high purchase price, the company paid its first dividend of $40,307 four years later, and has paid in total dividends to date $427,324.

The fact that initial development is limited to available capital is a reason why the large companies have opportunity to develop and produce oil at a minimum cost. Notwithstanding this, they have not done so, and very largely for the reason that operations are subject to too much system, red tape, and regulation. Drilling a well involves the solution of many and various difficulties which can be surmounted only through the prompt action and ingenuity of the driller. Consider a well drilled to a depth of 2000 or 3000 feet—often a half mile or more—and from six to three inches in diameter, with a string of casing weighing many tons, suspended, and which must be kept free to move up or down. In addition to this, a string of tools often more than fifty feet in length and weighing several thousand pounds must be kept in working order. If they are lost through a break in the cable, or a cave, they must be recovered through 'fishing'. Probably no other engineering operation requires more constant attention, skill, and ingenuity than drilling a deep well. No well can be drilled according to formulae. It is the energy and direct management of the smaller companies that has made it possible to sell oil at a profit through all the vicissitudes of the market, and has gained for the oil industry its credit of many millions in dividends.

The life of a property depends to a considerable degree upon capacity for production. Depletion of the oil in a property is a factor which must be considered in arriving at cost of production. It is obvious that the ratio of rate of depletion to rate of dividend must be less than unity in order that capital may be redeemed together with interest on the investment. M. L. Requa has pointed out, in an address before the University of California Mining Association, that if a company earns 10% per annum on a property which is reduced to zero value in ten years, the net result will be the return of the capital without interest. Theoretically, the more rapidly a property is exploited and the mineral exhausted, the greater will be the return upon the investment. This is manifested from the fact that petroleum or any other valuable mineral unrecovered from property which is being operated, represents dollars and cents of invested capital to regulate the rate of production so that the markets may not become congested and prices suffer. The Independent Producers Agency is at the present time working out this feature and has recently passed resolutions to the end that each of the companies shall have its capacity for production determined and its monthly runs pro rated therewith in accordance with market capacity.

Correlative to depreciation of property is the trouble caused through the agency of underground waters. Water is the natural enemy to oil and oil property, and the encroachment of water throughout the oil zones is an uncertain factor in determining the life of a property. Water encountered above the petroliferous formation may be cased off in drilling, and water underlying the oil-bearing stratum may be plugged off if drilled into. But it is the water occurring in lenses upon the strike of the oil sand which is the real menace, and in the majority of cases it is inevitable that at some uncertain future date it will displace the oil in the sands, driving it upward along the flanks of the anticline or monocline from property to property until it is exhausted.

In the December 10, 1910 issue of the *Mining and Scientific Press* I presented figures, as representative as possible, showing the cost of drilling. For a first well the material alone will cost $12,540. For drilling to 1000 ft., add to this from $4000 to $7500, for 2000 ft., add from $7500 to $15,000, for 2500 ft., add from $10,000 to $20,000. Figures representing the cost of drilling vary widely, according to economic conditions, methods of work, and the character of the formation. Some instances of variation in actual cost of drilling are shown below.

Field	Depth (feet)	No. of wells.	Av. time taken (days)	Average cost.
North Midway	1440	1	27	$ 8,750.00
do	1000	5	56	11,188.89

*Rotary.

‡Combination, rotary and standard.

†Third deepest well in the world; deepest drilled with cable tools.

Modern practice has greatly reduced the expense of pumping or lifting. First came the system of jacking the wells, that is, several wells were pumped through the agency of one engine transmitting its power by means of cables. This method admits counterbalancing the down-stroke of the pump in one well against the up-stroke in another. While this practice is applicable in some of the Eastern fields, it has not, as a rule, met with success in California for the reason that to get the best results from a well, different speeds of pumping are required. With the jack, all of the wells must necessarily be pumped at the same rate. Next, gas-engines were employed, utilizing the gas from the wells they pumped, gas which had before gone to waste, eliminating the consumption of fuel and water. The gas-engine is now extensively used throughout the Coalinga and Midway fields.

With the advent of electric power in the oilfields came the motor-driven pump. Twenty-two motors are now pumping in the Coalinga field and proving themselves efficient. They are designed for wells ranging in depth from 750 to 2500 ft. and are rated at from 20 to 30 hp. ½-hour rating, with from 6⅔ to 10-hp. continuous service. The lower powers are used for pumping, while the higher power is used for operations such as pulling tubing, sucker rods, pump, and bailing. With time as a factor, the motor possesses an advantage over steam or gas in pulling a well. Aside from a saving in labor, this is especially important for the reason that time lost, during a shut-down for cleaning a well, is against low cost of production. From a comparison of figures showing the consumption of fuel oil in pumping as against electric power consumed, and, not taking into consideration the cost of boiler water, which in itself is an important factor of expense, the price of oil at the well must be as low as 19.9c., in order to be equivalent to electric power at 1.5c. per kilowatt-hour, which is the maximum cost of the power. The following figures show the cost of pumping by steam and by electricity under equal conditions as regards gravity of oil and amount pumped in 24 hours:

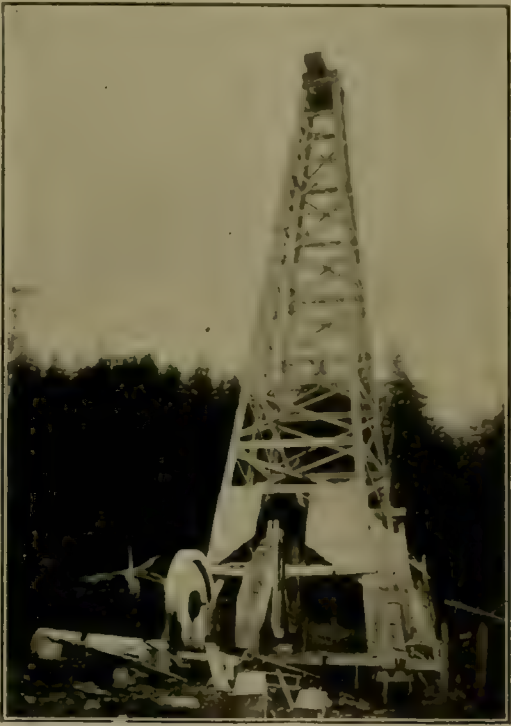
Depth (feet)	Oil burned (bbl.)	No. of wells	Fuel per well (bbl.)	Cost
1000	16	4	4	$1.40
1000	18	5	3.6	1.26
1000	20	5	4	1.40

Depth (feet)	Power kw., 24 hr.	Cost per day	Kw. per foot per day	Cost per foot
1000	53.3	$0.80	0.0533	0.08c
1080	69.6	1.044	0.0644	0.10c
1500	100.8	1.512	0.0672	0.10c
1950	133.3	2.00	0.0682	0.10c
2200	105.0	1.575	0.0477	0.07c
2200*	88.6	1.33	0.0403	0.06c
3000	192.0	2.88	0.064	0.10c

---

*Same as the preceding, but with walking beam counter balanced.

In pumping by means of the walking-beam, which is the method employed to raise oil from deep wells, a saving of 15½% in power consumption has been effected through the use of a counterbalance. Wear and tear on the machinery and engine are diminished because of the steadier action of the beam. With the counterbalanced walking-beam depth is the only factor in power-consumption, because of the friction and viscosity of the petroleum, which varies as the length of the column. Consider now the mechanics of the walking-beam, one end of which is cranked to the band-wheel and the other end supports the sucker-rods which lift the oil. The engine must lift by means of the beam, the weight of the rods (¾-in. rods weigh 1½ lb. per linear foot) plus the weight of the oil (which varies from 2.97 lb. per linear foot of 3-in. column for 14° gravity Beaumé, to 2.76 lb. for 25° gravity), and also take care of the friction and viscosity of the oil in the tubing. On the down-stroke the work done by the engine is negative, consisting of the gravity action of the rods minus their buoyancy minus the friction of the fluid on the rods. Upon determining the coefficients of friction and viscosity of the fluid, the difference in the up-stroke and down-stroke of the beam may be exactly counterbalanced. It is remarkable that throughout the fields very little counterbalancing has been attempted.



DRILL RIG AT KATALLA, ALASKA.

Another factor in the economy of oil production is the water-heater. Simple in construction, consisting of a piece of casing and a coil of pipe, it should be used in connection with every boiler in the fields. Through close observation of many experiments, it has been found that a saving of 20% in fuel-consumption may be made.

Pumping or lifting expenses should be so posted and tabulated that they may not only serve as a comparative guide to the superintendent, but also indicate to the foreman where to concentrate his efforts to cut expense. I have selected for recommendation the following forms used by a successful West Virginia company. Form No. 1 is given to each foreman of the company, so that he can make comparison of his receipts and expenditures each month and see how much it is costing to lift each barrel of oil from his property. This monthly sheet is posted in Form No. 2 for the use and guidance of the superintendent. At a glance he can see the decrease or increase in the various items month for month, and can take proper action to the end that the oil may be produced at the least possible cost.

FORM NO. 3.

I have arranged the third form to incorporate the features of forms No. 1 and 2, and at the same time to set forth every item of expense and outlay in the production of oil from the time the original investment is made. With this form posted monthly, the cost of production is constantly in view. In estimating cost of production, time is the greatest factor of all. As development work proceeds, cost of production becomes less and less, and, when development has been completed, cost of production should be at a minimum. Companies that have completely developed their property are producing oil at a present cost of about 8c. per barrel. Other companies having large properties with from 40 to 60 wells producing about 3000 barrels of oil daily, but with development work still in progress, are producing oil at a cost of about 14c. per barrel, and so up to companies that are producing at a cost of $4 or $5 per barrel. So cost of production means but little when applied to all the producing companies, and for a like reason it is useless to attempt to determine an average cost of production.

The Federal Tax as Applied to Mining Corporations

We have received inquiries regarding the operation of the special Federal excise corporation tax and its bearing on corporations engaged in mining, and especially the right to charge off as depreciation the ore taken out of the mine. At the present writing there have been few decisions on the question, but litigation is now pending in the Federal courts which will clear away some of the difficulties. The subject is of sufficient interest to many of our readers to warrant publishing in full that portion of the regulations issued by the Commissioner of Internal Revenue which has a special bearing on corporations owning and operating mines. The following recent pertinent comment on this phase of the subject by an official in authority will also be of interest:

"Relative to an allowance of depreciation in the value of the mining property because of the depletion of the deposits of ores, thus exhausting the capital assets of the corporation, it is believed that the regulations adopted can be applied with results entirely just both to the taxpayer and the Government. Of course, claims of corporations based on the theory that the value of the mineral in the ground is exactly the value of such minerals as placed in the commercial channels, minus the cost of production, thus divesting the corporation of the attributes of a going concern and placing it in the attitude of simply liquidating profits already earned, is not acceded to. * * *

"The position of (the Federal officials) does not admit of constructive loss in the conduct of a business, such as the removal of the products of nature, when in fact such business is carried on at an actual profit."

Many of our readers will doubtless wish that the regulations might be translated into twentieth-century language, making them intelligible to the man of average mentality. The energy of a legislative body should not be largely absorbed in devising a law which the courts cannot upset, nor the wisdom of judges be concentrated upon the detection of misplaced commas and overlooked formalities of procedure.

REGULATIONS

72. Cost of drilling new wells by oil corporations is considered betterments and additions to the capital assets of the corporation. The expense of drilling dry wells may, however, be charged to profit and loss.

76. Deduction on account of depreciation must be based on lifetime of property, its cost, value, and use.

DEPRECIATION IN MINERALS, OILS, ETC.

80. In case of corporations whose business consists in part or wholly of mining, producing, and disposing of deposits of nature (ores, coals, gas, petroleum, and sundry minerals) the conduct of such business will be understood to comprehend two classes of gains or losses, viz:

(*a*) The gain or loss resulting from the sale of capital assets, *i.e.*, either the increment, or the loss, arising through possessing over a period of time the investment in the same.

(*b*) The trading or commercial gain attached to the conduct of the industry, the employment of working capital, the effort and risk involved.

81. In the ascertainment of net income deduction will be allowed for depreciation arising from exhaustion of deposits of ore, mineral, etc., and for depreciation and obsolescence of improvements, in accordance with general regulations respecting depreciation allowances, on the basis of the original capital investment cost of the properties concerned to the company reporting.

82. A further deduction will also be allowed, through not including the same at all in the item of gross income (item 3, Form 637), for the unearned increment represented in such properties as at January 1, 1909, which will be determined in general as follows:

83. An estimate should be made as of January 1, 1909, of the fair market value at that date of the minerals, etc., in deposit. This estimate should be formed on the basis of the disposal value of the minerals in total and exclusive of value of improvements and development work. This valuation should also be reduced to a unit value, per ton, barrel, etc.

Note.—Values as aforesaid should not be estimated on the basis of the assumed salable value of the output under current operative conditions, less the actual cost of production, because, as heretofore stated, the selling price under such conditions comprehends a profit both for carrying the investment in minerals, improvements, and working capital and for conducting operations in respect of production and disposal of product. The value to be determined as stated must be on the basis of the salable value of the entire deposit of the aggregate units of minerals considered *en bloc* if disposed of in that form. Nor must such valuation comprehend any speculative value which might attach to a sale of the minerals *en bloc*, *i.e.*, a value which might be obtained on the ground that the future would develop a much greater reserve of mineral deposits than were believed to exist at the time estimate as of January 1, 1909, was formed. Any value of this latter character would attach obviously to such additional reserves when developed in future.

84. The unit value as of January 1, 1909, ascertained as above outlined, would indicate the value to be attached at that date to the capital assets disposed of during any calendar year succeeding, and should be used in determining the unearned increment at January 1, 1909, which may be excluded entirely from the item of gross income, as before explained, in following manner, viz:

Value at January 1, 1909, determined in manner outlined, of minerals, etc., which may be removed and disposed of in any year subsequent thereto.......$ ——
Less the following:
(*a*) Proportion of depreciation charge applying to exhaustion of minerals disposed of, ascertained as first explained herein on basis of original cost.....$——
(*b*) Royalty paid, if any, on minerals disposed of ....$——
—— $ ——

Balance, being unearned increment at January 1, 1909, to be excluded from gross-income item .... $——

85. The precise detailed manner in which the estimate of value of minerals, etc., as at January 1, 1909, shall be formed, must naturally be determined upon by each corporation interested, but formal record of such estimates, together with all sustaining information, should be carefully filed so as to be readily accessible for reference. Values as stated, as determined at January 1, 1909, should be used in compilation in all subsequent years' excise-tax returns. The question as to whether it subsequently develops the property possessed a greater quantity of mineral, etc., reserve than was in the aggregate estimated as of January 1, 1909, is immaterial. Any excess which may be developed will be considered as possessing the same value at January 1, 1909, as that which then may have been known to be in the property.

86. Each excise-tax return (Form 637) should be accompanied with the memorandum setting forth the extent in amount of the exclusion made from the item gross income for unearned increment realized during the year, as above outlined.

87. As the amount to be deducted for depreciation (paragraph 2 preceding) is to be formed on basis of the estimated reserve of minerals, etc., it follows that if it develops such estimate is understated, the cost investment in the capital asset may be wholly extinguished before all mineral reserves are removed. When this is reached, further deductions for exhaustion of minerals should be discontinued, but, in such event, it will be noted, the allowance for unearned increment which is to be excluded entirely from gross income will be correspondingly increased.

88. In case of corporations leasing mines and paying royalties on minerals, etc., removed, the royalties paid are to be treated as expenses and deducted in ascertaining net income, as provided in general regulations. Any leasehold investment which the operating corporation may have in such properties, either through a payment originally made for acquirement thereof or for improvements made upon the property, to be accounted for in accordance with regulations governing depreciation allowances and disposition of capital assets.

89. In respect to properties of the character in question which may be acquired by a corporation after January 1, 1909, a deduction will be allowed only as to depreciation arising from exhaustion based on original cost; no exclusion from gross income can be made for unearned increment, as profit arising in sale of such capital assets applies wholly to the period subsequent to January 1, 1909.

Iodide Method of Copper Determinations

By L. D. McClure

As my experience in using this method has been so satisfactory and the results obtained, during a period of several years, have been so uniformly exact, it is my desire to give, in detail, to those who may be interested, a simple and rapid-working scheme which I have employed in my work where a large number of copper determinations are made daily from churn-drill and mine samples, at the Live Oak mine, Globe, Arizona. The scheme, with a little practice, will be found more rapid than the permanganate or electrolytic methods, and the results are exact within very narrow limits of experimental error.

I will endeavor to explain in a lucid and concise manner just how I carry out my daily work in the laboratory, so that no difficulty will be found in following and working out each successive step of the process, as it is employed in actual practice in handling a large number of samples each day. The Live Oak ore has a copper content ranging from 2 to 5%, in the form of disseminated chalcocite in silicious schist. In handling more complex ores and furnace products, modification of the process would be advisable.

Method of Standardizing.—Prepare a solution of sodium thiosulphate, containing 40 gm. of pure crystals to 2 litres of distilled water, and proceed as follows: accurately weigh three portions of 0.10 gm. each of pure copper foil into beakers of 300 c.c. capacity; add about 1 c.c. of strong nitric acid to each beaker; place upon the hot plate, and evaporate off the excess of nitric acid until almost neutral copper nitrate is obtained, which will be indicated when by tilting the beaker the solution will flow rather sluggishly over the bottom. The evaporation must not be carried beyond this point, as there is danger of producing some insoluble basic copper nitrate. Remove the beakers from the hot plate, dilute with about 25 c.c. of distilled water; stir in enough of a saturated solution of sodium carbonate to cause a slight precipitate; add 2 c.c. glacial acetic acid and then 3 or 4 grams of potassium iodide in crystals. By gently shaking the beaker the potassium iodide will dissolve almost instantly. Cuprous iodide will be precipitated and iodine, exactly proportional to the amount of copper present, will be liberated, and be held in solution in the excess of potassium iodide, imparting to the solution a reddish brown color, according to the reaction:

$$2Cu(C_2H_3O_2)_2 + 4KI = Cu_2I_2 + 4KC_2H_3O_2 + 2I$$

Proceed at once to titrate. Run the sodium thiosulphate solution into the beaker, constantly stirring until the iodine solution changes to a faint yellow color, and then add sufficient starch solution to produce a deep-blue coloration. Continue the titration cautiously, drop by drop, with constant stirring. Stop when the solution assumes a violet color and continue stirring for a few seconds. If the violet color does not rapidly change to a creamy white tint at this point, another drop from the burette will be required.

It will be found from the burette readings that about 20 c.c. of the thiosulphate solution has been required for each of the three beakers, or 1 c.c. equals 0.005 copper, approximately. If, however, there should appear a slight variation in the three readings, I use the average of the three readings to calculate my standard.

Treatment of Ores.—Weigh out 3 grams of low-grade ore, or proportionately less for ores of higher grade, into a 300-c.c. beaker. Add from dispensing burettes 10 c.c. strong nitric acid and 5 c.c. sulphuric acid. Put the beaker on the hot plate and boil nearly to dryness. Remove the beaker; cool somewhat; add 2½ c.c. sulphuric acid, which produces a very satisfactory degree of acidity for the copper precipitation; dilute with 25 c.c. distilled water; stir with a rubber-tipped glass rod to loosen any cake that may have formed on the bottom of the beaker. Place the beaker again on a warm part of the hot plate, and digest for about 10 minutes to bring the sulphates into perfect solution; then filter through a 15 cm. filter paper into a 150-c.c. beaker. Wash the insoluble residue on the filter twice with boiling water. Then pour filtrate back into the original beaker and rinse the filtrate beaker with a little water.

The filtrate should now measure about 75 c.c. and should fill the beaker to about one-fourth its capacity. Next place in the bottom of the beaker a piece of aluminum 3 in. long, 1 to 1½ in. wide, and bent at right angles at or near the middle, so that one-half lies in the bottom of the beaker and the top of the other half extends a little above the surface of the solution. Cover the beaker and boil for about 10 minutes, when the copper will be precipitated; the solution will be perfectly colorless; and the aluminum will appear clear and bright. During the last few minutes of boiling, the sulphuric acid attacks the aluminum vigorously, and the minute bubbles of hydrogen gas which are given off have a tendency to free the aluminum of all small adhering particles of copper.

Now take the beaker from the hot plate, and remove the aluminum from the solution with the forefinger and thumb of the left hand, at the same time playing a small jet of cold water upon it to cool and wash off any adhering particles of copper. Carefully decant the solution, leaving the copper on the bottom of the beaker, and wash twice by decantation with cold water. Dissolve the copper in about ½ c.c. of strong nitric acid, and place the beaker again upon the hot plate to evaporate the excess of nitric acid, and then proceed in the same manner as described for standardizing. The starch solution is made by rubbing 1 gm. of cornstarch into a smooth paste with a little distilled water, diluting with distilled water to 200 c.c., and boiling the solution for a minute. Cool before using. The paste may be kept for some time if a small quantity of lysol or other antiseptic be added to prevent the growth of mold.

The Murex Plant at Broken Hill

The Murex plant installed at the Broken Hill Block 14 Mine is reported to have secured a recovery of 80% of the metallic content of the ore. To this stage the process has worked well. The problem that now has to be solved is whether the de-oiling and the de-magnetizing of the product obtained can be done efficiently and cheaply. Whatever may be the outlook in this direction, the work done with the process on low-grade copper ores is so satisfactory that a unit is to be erected on one of the biggest mines in Australia that has large supplies of such ore, to see whether the process can be profitably used by it. News from London is to the effect that 2½% copper ore from the Cordova mine in Spain was treated with a recovery of 92%. Then 2000 tons of mixed tailing, with a full quota of slime, the whole assaying 1¾% copper, was treated, and an extraction of 86% obtained. The total recovery from the ore is reported to have been 93½%. It is understood that a 200-ton plant will be put up at Whim Well claim, in West Australia, so that mining men on this side of the world will soon have several units demonstrating the merits of the process on a working scale.—*The Australasian.*

Rawhide Queen Mill

The milling plant of the Queen and Coalition mines, Rawhide, Nevada, which was completed and put in operation several weeks ago, has the capacity of 50 tons of ore per day, and an extraction of 90% of the gold and silver is being made. The ore treated is well oxidized, and is being mined by lessees, there being nine producing leases in the property. Mining on company account, also, is expected to begin in a short time. The ore is passed through a Dodge rock breaker and elevated to the ore bin, above the ten 1050 lb. stamps, having 16 to 20-mesh screens. The pulp passes next to an Akins classifier, the sand from which goes to the tube-mill, and is then elevated by a Frenier pump to another classifier, the sand from which is returned to the tube-mill. The whole product now passes to the amalgamating pans, in which all of the metallics, both gold and silver, are recovered. The pulp then passes through an automatic sampler to the first Dorr thickener, thence to two successive Trent agitators. It is pumped from the last agitating-tank to the second Dorr thickener, the pulp being drawn out at the bottom of the latter to a short elevator, by which it is raised to an Oliver filter. The precipitation takes place in three 9-compartment zinc-boxes. The tube-mill used is of the 6-ft. Hardinge conical type. Two tanks fitted with Dorr thickeners are each 20 ft. diam., 12 ft. deep; the two tanks having Trent agitators are each 20 ft. diam., 16 ft. deep; two gold-storage tanks, 12 ft. diam., 6 ft. deep; two sump tanks, 20 ft. diam., 6 ft. deep; and one storage tank for solution, above the stamps, 16 by 12 ft. The power at present is supplied by two Fairbanks, Morse & Co. gasoline engines, 50 and 32 hp., respectively, in which distillate is used as fuel. The intention is, however, to equip the mill, using electric power, in the near future, securing power from the electric line which is within half a mile of the plant.

RAWHIDE QUEEN MILL.

Refining and Smelting at Port Kembla

Operations at the works of the Electrolytic Refining & Smelting Co. of Australia, Ltd., at Port Kembla have assumed large proportions, the electrolytic copper produced by this company having already established a wide reputation for purity (says the *Sydney Morning Herald*). For the year ended December 1910, the company produced metals as follows: gold, 112,485 oz., valued at £476,653; silver, 65,821 oz., valued at £7130; copper, 9952 tons, valued at £583,027. The total value was £1,066,810. The greater portion of the output came from the blister copper produced at the Mount Morgan mine, Queensland, but the refining also proved of useful service to a number of small producers in the State. The metals obtained from the ores mined in New South Wales and treated at these works, are estimated at: gold, 808 oz., fine; silver, 3994 oz.; copper, 929 tons—of a total value of £57,700. In August a contract was entered into between the Mount Lyell company and the Electrolytic company, under which the refining of the blister copper output of the former company will be carried out at Port Kembla instead of America as formerly. To carry it out the present works, which cost some £137,000, are being duplicated. The present capacity is 14,500 tons per year of refined copper. This will be increased to 23,000 tons per annum, which means employment of some 500 men, as compared with about half that number at the present time. With the works in full swing, the coal consumption of the company will amount to 60,000 tons per annum, and the consumption of water to 40,000,000 gal. The shipment of Mount Lyell blister to Port Kembla means that the electrolytic works will receive steamers regularly from every State in the Commonwealth, and the blister copper produced at Mount Lyell will be sent to Port Kembla to be refined, and the product despatched to European and other markets for sale. The hope is now expressed locally that the Works Department will have the railway carried into Port Kembla.—*Queensland Government Mining Journal.*

Southern Appalachian Gold Production

When the early Spanish explorers came to America they were shown by the Indians rich nuggets and ornaments of gold which came from the southern Appalachian region. Later, in the seventeenth century, the Spanish mined for gold in Georgia. During the eighteenth century very little attention was given to mining anywhere in the Appalachians, although it is supposed by some that gold was found in North Carolina before the Revolutionary War.

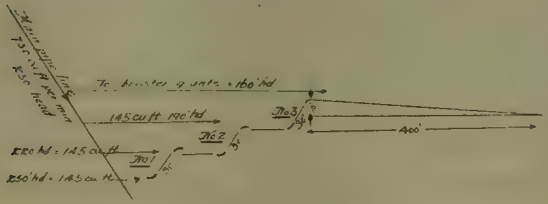
Just at the close of that century placer gold was discovered in Cabarrus county, North Carolina, and, after that, prospecting was energetically carried on. The first reported production from South Carolina mines was in 1829, and the gold produced was said to be worth $3500. From that time until the Civil War, mining was an important industry of the region, and although the rich fields of California lured many from these deposits of lower grade, the indirect result of the California excitement was a stimulation of mining activity in the East. During the war, and for several years after, little gold mining was done in this section, but in the seventies, eighties, and nineties the condition of the industry improved. At the present time gold mining in the central portion of the Carolinas is not flourishing on account of the decreasing supply of free-milling ore and the inability to extract the gold from the lower-grade sulphide ore at a profit. Production will probably continue, nevertheless, for many years.

Waldemar Lindgren, in his 'Notes on the Dahlonega Mines', published as a portion of Bulletin 293 of the U. S. Geological Survey, states that the total production of gold and silver in Georgia, from the discovery of gold near Dahlonega in 1828 to 1900, was between 16 and 17 million dollars, and of this amount the largest portion was produced by the mines of Lumpkin county, in which Dahlonega is situated. The total production of gold in the Appalachian States from 1800 to 1900 is estimated at $47,000,000. For the last few years the total annual production has been about $300,000, while the production of Georgia has varied from $60,000 to $130,000, the former figure being recorded in 1903. The value of gold and silver mined in Georgia in 1910 was about $26,000.

It is an interesting historical fact that the earlier stamp-mills of the Rockies and the Sierra Nevada were modeled after the successful mill first set up and perfected in the Southern States. The best gold miners of the country, a that time, were also those of the Southern States, and the success in mining and milling gold in the far West in these earlier days is largely to be credited to these pioneers from the South. The first gold miners in the Appalachians had received their training in Europe and they passed on their knowledge and experience to those who brought into being the 'Golden West.' The value of the gold deposits attracted so much attention that fertile minds were soon at work, and milling methods were greatly improved within a short while after the discovery of gold in California.

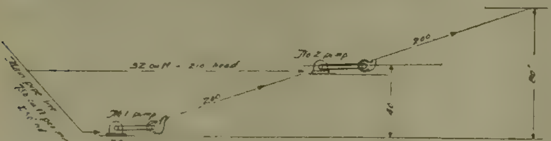
Elevating Sand

A practical problem in elevating wet sand is furnished by a recent case where it was necessary to elevate 10 tons per hour of wet sand against a vertical (static) head of 80 ft., the length of the pipe-line or ditch, whichever was used, being 400 ft., the particles not exceeding ⅛-in. diameter. For this purpose 500 miner's inches of water was available, working under an effective head of 250 ft. The question to decide was whether to use hydraulic elevators or centrifugal sand-pumps.



HYDRAULIC ELEVATORS.

In the first place, hydraulic elevators have an efficiency of about 16⅔%; in other words, they are capable of lifting water and gravel to a height not to exceed 16⅔% of the effective head of the supply water. Under these circumstances it is at once seen that the total lift possible applying a head of 250 ft. at one point is only a little more than 41 ft. To use hydraulic elevators at all for this purpose it would be necessary to handle the sand and water in three stages, each stage taking care of a lift of 30 ft. As the duty of a miner's inch is ordinarily considered to be 2 cu. yd. per day of 24 hr., for the first stage 90 miner's inches of water would be required to handle 10 tons per hour under a head of 250 ft. against a total lift of 30 ft. In the second stage the same volume of material would be handled with the same quantity of water under a head of 220 ft. In the third and last stage the same quantity of material would be lifted with the same quantity of water under a head of 190 ft., making three outlet branches at different points from the main pipe-line. Then the problem becomes one of sluicing the water and sand for 400 ft. with a total fall in 400 ft. of 10 ft. As the natural velocity due to gravity would not be sufficient to move this volume of material at a sufficient speed to prevent the sand from depositing on the bottom of the sluice or flume, it would be necessary to install two booster giants, which would be placed in the flume, using the main water supply for accelerating the speed of the discharge. The first cost of such outfit would be high, as the three elevators, together with the necessary suction attachments, up-raise pipe, and two booster giants, would cost approximately $3000.



CENTRIFUGAL PUMPS.

It would be better to use specially constructed and designed centrifugal sand-pumps operated by means of water-wheels and do the lifting in two stages, figuring upon a dilution of 4 to 1. The quantity of pulp that each pump would be required to handle would be approximately 200 gallons per minute. The static head being 80 ft., the friction head would be 30 ft. through 400 ft. of 4-in. O. D. casing, making a total head to pump against of 110 ft., which would be divided between two pumps working against a total head of 55 ft. each. For this purpose two 10-in. diam. specially-designed split-casing pumps with manganese steel runners and manganese steel lining would be required. These pumps would operate at 1500 r.p.m. and each pump would be belted to an 18-in. enclosed-type tangential water-wheel, the first one developing 10 hp. with 25 cu. ft. of water per minute under 250-ft. head, and the second one developing 10 hp. with 31 cu. ft. of water per minute under 200-ft. head. The two specially-designed centrifugal pumps would cost about $250 each and the water-wheels about $150 each. In making comparisons between the two propositions you will note that the main pipe-line will require but two branch outlets for the pumping proposition, as compared with three for the elevator proposition. Without a sketch showing the lay of the land, it cannot be known how either of the schemes will adapt themselves to the conditions on the ground. But of the two the pumping scheme is the more flexible, as the discharge from the No. 1 pump can empty into a small sump leading directly into the suction of the No. 2 pump. The accompanying illustrations will serve to explain the two ideas. It is obvious that the pumps will be far more satisfactory, will use less water, cost less money, and will have much greater efficiency.

Industrial Lighting

The lighting of ore-dressing plants and smelters, as well as the interior of mines, brings up problems that require considerable thought and skill to secure the maximum results at minimum expense. The following from the *Journal of Electricity, Power and Gas* is of interest in this connection and may serve to direct the attention of superintendents to the desirability of attention to the matter of the proper placing of lights.

The National Association of Manufacturers' committee on ventilation, heat, and light finds that the effect of varying character of artificial light on the quantity and quality of product produced may be and frequently is great, and, consequently, affects the cost of production to a very considerable extent; and feels that it is a matter of ordinary observation to those at all expert in the question of artificial lighting that factory lighting, generally speaking, is not at all what it ought to be. The following statement is a brief summary of the principal defects which are ordinarily to be found.

In very many cases there is insufficient illumination. This condition, however, is rapidly improving as the result of the advent of lamps of various kinds of much higher efficiency than anything that has been available in the past. It is a fact, however, that in a great many cases where the absolute amount of illumination is sufficient, the light is nevertheless exceedingly unsatisfactory for various reasons. If the light falls on the work from the wrong direction, not only is there great liability that awkward shadows of the machinery or of the operative's body will interfere with the work, but, in addition, if light is reflected from polished portions of the machinery or from the work itself directly into the eyes of the operative, the results will be anything but satisfactory. Failure of light to come in the right direction is often distressing to the eyesight, and it follows that, since it may cause the operative to work in an unnatural position, it may result in unnecessary bodily fatigue as well. Such unfortunate results are often obtained if an attempt is made to light a workroom with too few sources of light. Under these conditions, although some operatives may receive a satisfactory light, others are extremely likely to get the light in the wrong direction, with the unsatisfactory results above enumerated.

Another most common defect in factory lighting is the exposure of the eyes of the workers to the direct beams of very brilliant lamps. The use of bare incandescent lamps is almost invariably not only insufficient, but also dangerous. Generally, however, there is no difficulty in avoiding this trouble if proper care is taken. Still another defect often seen is either too great or too little contrast in the illumination of rooms. The former of these is by far the most common, and as an example might be given work on sewing machines, where individual lamps with opaque reflectors are supplied which brilliantly illuminate the machines, but leave the rest of the room in comparative darkness.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Concrete Mortar Blocks

The Editor:

Sir—In the matter of the best type of concrete mortar blocks to be adopted, brought up by 'Puzzled Engineer' in your last issue, it would seem probable that each of the three types he describes would give entirely satisfactory results, and unless a comparison of the types built side by side and operating under identical conditions could be made, it would be more a matter of personal preference than actually demonstrated superiority which one was "the best." The evolution of foundations from the wooden block capped with a blanket to the massive, highly dense concrete pier, has been brought about by the acceptance of the fact that the greater the inertia and density of the anvil under the dies the higher the efficiency of the stamps; prejudice as to inability to construct concrete which would not disintegrate, and that excessive breakage of battery parts would result, having been overcome. It would seem, then, better to adhere to a type which fulfills the condition of greatest inertia and density under the dies. This is found in Form 1.

The objection that the anchor bolts are not as accessible for renewal and replacement as in the other forms shown should not be given such serious consideration. The writer's experience has been that these bolts when made of 1½-in. Norway iron upset to 1¾ in. for the threaded ends, do not break; at least their life can be counted on for a period of years, and if it becomes necessary to replace them, the mortar can be cleared and pushed back and the change made with very little loss of time for the battery. It would seem an unnecessary refinement to provide for a condition which may never arise, and which amounts to so little when it does. The impression your inquirer has about the mortars in Form 1 not being tied to the main body of the block is, in two of the mills quoted, in error. This type of foundation has individual pockets for the lower end of the anchor bolt, and individual straining blocks of wood. A description with detailed drawings showing foundations of this type designed by me during 1905 for one of the mills of the Oriental Consolidated Mining Company of Korea appeared in the *Mining and Scientific Press* of May 11, 1907. At the time J. B. Fleming designed the Goldfield Consolidated mill he informed me of his intention to make use of the same type of foundation, reinforcing the web between the pockets. I believe he has duplicated the Goldfield foundation in the Nevada Hills plant.

San Francisco, July 2. CHARLES D. KAEDING.

The Editor:

Sir—In my opinion it is desirable to so place anchor-bolts in foundations of all kinds, that in case of breakage of a bolt the broken ends may be at once removed and a new bolt substituted, and this should be possible, in the case of stamp-mill mortars, without the removal of the mortar from its place, or even the loosening of any of the other bolts holding that mortar. To render this possible the bolts must be so placed with reference to the mortar, that the broken ends, or if necessary, the entire bolt, can be removed; therefore the direction of the bolt in the foundation should be such that the bolt will clear the mortar when withdrawn. It is a good idea to place the bolts in pipes, as this facilitates repairs and renewals. In my experience the breakage of anchor-bolts of stamp-mill mortars is due usually to the use of an inferior steel, or, more commonly, to using bolts of too small diameter. These bolts should not be less than 1½ in. diam: and 2 in. is better, for a rod of this size admits cutting a heavy, deep thread, one which will not readily strip, and at the same time [illegible] of breakage under the heavy pounding and the constant vibration to which these bolts are subjected, more, perhaps, than any other bolts around machinery foundations. I think the bolts should be placed vertically, and under no circumstances at an angle. If they extend vertically downward from the mortar base they will have plenty of clearance, and will be at least 30 in. apart, transversely, and about 14 in. longitudinally, thus affording abundant concrete for holding. The employment of a piece of timber at the lower end of the bolt, to give it a certain amount of resiliency, is no doubt good practice, but I think the use of spring washers, similar to those in use on the bolts holding the fish plates on some railroads, will give as good results, while not taking up one tenth of the room required by the insertion of the block of timber.

Berkeley, July 3. WILLIAM H. STORMS.

Errors in Mine Sampling

The Editor:

Sir—In your issue of June 24 you make editorial comment upon the fact brought out by Morton Webber, that in sampling a mine the error is usually a positive one, giving higher results than the actual facts. According to the theory of probability it is to be expected that the resultant error of a series of errors—a series of assays, for example—would as often be negative as positive. Since this seems not to be the case it must either be because the negative errors are fewer, or smaller than the positive errors. A frequent suggestion is that the rich ore is softer than the barren gangue, hence a super-normal proportion of it is included in the sample. But every engineer knows of this, and it is only to be expected that sometimes, in the endeavor to prevent it, too small a proportion of the valuable mineral would be included. And, on the other hand, it is not always true that the valuable mineral is softer. In gold quartz veins, just the very case where the greatest difficulty is met in the attempt to secure accurate results, the rich quartz is often no softer than the barren. Another possible explanation is the optimism of human nature, shown in the common experience of underestimating the cost of a journey. Of course, allowance must be made for the waste rock broken in stoping, but I am referring to Mr. Webber's case (3), where sampling indicates a fictitious high value. There do not exist, so far as I know, any good reasons why careful sampling work should indicate a fictitious value. Perhaps valuing engineers can give me some.

Los Angeles, June 26. A NEAR-GEOLOGIST.

Titrating Cyanide Solution in the Presence of Silver

The Editor:

Sir—The publication of the interesting article by E. M. Hamilton, dealing with the sulphocyanate determinations in the presence of silver, prompts me to send you extracts from some notes that I made at the time of starting up a high-grade silver-ore cyanide plant in Mexico some little time ago. Daily titrations showed that the solution entering the zinc-boxes was invariably 30% lower in total cyanide than the effluent. Free cyanide titrations, on the other hand, showed no difference at either end.

The explanation was simple, and I accounted for the difference by the fact that the incoming solution carried large quantities of silver in the form of the double cyanide of silver and sodium. The cyanide in this compound would not appear in an ordinary estimation for total cyanide made with the aid of alkaline iodide indicator. During passage through the boxes, however, the silver was liberated and the double cyanide of zinc and sodium formed. The available cyanide in the latter could then be titrated for by ordinary means. The absence of copper made it possible, by a comparison of total cyanide titrations of incoming and outgoing solutions, to estimate, with fair accuracy, the amount of silver which was being deposited in the boxes.

Uruguay, South America, May 25. A. W. ALLEN.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

STEEL TOOLS may be kept from rust by placing a lump of freshly-slaked lime in the drawer or case where they are kept. The lime will absorb a great deal of moisture.

TO PRESERVE iron against rust, immerse it for a few minutes in a solution of blue vitriol, then in a solution of hyposulphite of soda acidulated with hydrochloric acid. This gives a blue-black coating which neither air nor water will affect.

CREOSOTE is the most effective preservative for wood which is buried in the earth. Experiments with telegraph poles have shown that it is much more effective than other chemicals used as corrosive sublimate, copper sulphate, and zinc chloride.

OIL LANDS in the public domain can be located as ordinary placer claims, and the laws governing both are the same. Large areas of oil lands have been withdrawn from entry, and Congress is likely to impose restrictions upon the location of remaining oil land.

CONCRETE floors can be given a smooth surface like wood but non-inflammable by coating them with a mixture of magnesite, asbestos, talc, and sawdust, with a binder of chloro-magnesium, etc. The materials are mixed just before using; after the floor is dry it can be waxed.

WHERE water springs up and sinks again within the boundaries of a valid mining location, the owner of the claim is entitled to said water, provided it does not flow in a well defined underground channel and has not previously been made the subject of a valid appropriation.

PRESSURE GAUGES are valuable in detecting abnormal conditions in compressed-air pipe-lines. An accurate gauge placed at the air-receiver and another close to the machine where the air is applied will detect large losses of pressure, which can be remedied by increasing the size of the mains.

STEEL TOOLS may be tempered by using a mixture of one pound of mutton fat, or whale oil and one pound each of beeswax and resin. Put into a kettle and heat up to a boiling point, stirring it once in a while. When thoroughly mixed it is ready for use. Heat the steel till the scale rises a little, then immerse in the oil. When cool, heat over a slow fire till cherry red in the dark.

KAOLIN finds little market on the Pacific Coast, as it is used largely in porcelain manufacture and but little of this is done west of the Mississippi. At times there is a demand for [illegible] in the manufacture of alum, and for this purpose it commands $6 to $8 per ton of kaolin or $4 to $5 per ton of ordinary kaolin. Unless a deposit has an exceptionally favorable situation for working, it can not be profitably exploited.

A GOOD cement for fastening tools into handles, or setting small parts of metal or other material, is [illegible] to a paste. [illegible] When fastening [illegible] handles it is [illegible] by pressing it into the handle. This method is strong and durable.

THE PROPER preparation [illegible] nitric acid. Mix [illegible] the mixture, and it is ready for use. Cover the parts that are to be [illegible] with melted beeswax; when cold write the [illegible] on the wax down to the metal with a sharp instrument, then apply the mixed acids with a feather, carefully filling each letter. Let it remain from one to ten minutes, according to appearance desired, then throw on water, which stops the process, and remove the wax.

ALUMINUM will put an edge on fine cutting steel work. It acts exactly like a razor-hone of the finest quality. When steel is rubbed on the aluminum, as, for instance, in honing a knife blade, the metal disintegrates, forming an infinitely minute powder of a greasy, unctuous quality that clings to steel with great tenacity and thus assists in cutting away the surface of the harder metal. So fine is the edge produced that it cannot be made finer by a strop, which, if used in the ordinary way, merely tends to round the edge.

CHANGES can be made in drawings by the following method. From the original drawing make a brown print, using a thin, tough paper. This gives a print with clear white lines on a brown background, the brown being impervious to light. Paint out on this print, with ordinary drawing ink, the lines not desired on the changed drawing, after which make a second brown print from the first. The print thus obtained has dark brown lines on a white background. Draw in on this print the changes, and the desired new drawing results, from which blue-prints can be made.

GRAPHITE is graded largely on the carbon content, but also on the amount of iron and silica present, the texture, the color, and the brightness of the material. Different grades contain from 75 to 95% carbon, and the price of domestic amorphous graphite ranges from $5 to $25 per ton. Domestic crystalline graphite brings 1 to 9c. per pound. The United States consumes about one-third of the world's supply and considerable quantities are imported from Ceylon, Austria, Bavaria, and Mexico. Provided grade and shipping facilities are satisfactory there should be opportunity to market additional material.

HYDROCHLORIC ACID is usually made from sodium chloride and sulphuric acid according to the following formula: $2NaCl + H_2SO_4 = 2HCl + Na_2SO_4$. The HCl gas evolved is absorbed in water forming a solution, when concentrated at 15°C. containing about 40% HCl. The sodium sulphate formed at the same time is a by-product, but has a commercial value and is used extensively in the manufacture of glass. Hydrochloric acid can also be made synthetically from chlorine and hydrogen, and its production in this way is now being made to a limited extent as a by-product in connection with the electrolytic production of caustic potash.

MICA is used for a great variety of purposes in the form of sheet mica and ground mica. The former is the more valuable and sheets four inches or over in dimension are available. Sheet mica is used by manufacturers of electrical machinery and by stove makers. The larger companies own or control their own mines. Ground mica is used in the manufacture of wall-paper, paints, lubricants, fire-proofing, in manufacture of electrical equipment. The markets are mainly in the East, and the supply comes principally from North Carolina, South Dakota, and Georgia. To get in touch with prospective buyers write to some of the mineral and metal brokers listed in our advertising pages.

A METHOD of reclaiming dross tin or lead is to introduce a stick of green wood into the kettle and allow the gases that are driven off from the wood to bubble up through the molten metal. The metal must be heated to a red heat, as the affinity is very great at such a temperature. It would be impossible to reduce the oxide under these conditions as fast as it is formed. The right heat for the operation is somewhat over the actual melting point of the metal, but below a red heat. The stick of green wood is used because gases are given off which aid considerably in the reduction of the oxide. Dry wood does not give as good results. The operation usually takes several hours for ordinary thick lead or tin.

Special Correspondence

KALGOORLIE, WESTERN AUSTRALIA

Progress Notes for the Month — Total Output — Royal Commission on Miners' Diseases — Production of Principal Mines for April.

Nothing of note occurred during the past month, except that the Horse-Shoe continued drilling across its property at 2800 ft.; the Kalgurli company has reduced the grade of its ore as a result of poorer showing in the bottom levels; at 150 ft. in the main shaft of the Bullfinch, 48 in. of ore worth $29 was cut in sinking; the vein on No. 7 level in the Lancefield is 216 in. wide, $10 per ton; on the evening of April 24 the head-gear and breaker-bin at the main shaft of the Lake View Consols was somewhat damaged by fire, although work was continued next day as usual; the Lake View & Star mines' reserves are announced as 156,555 tons, worth $6.78, and 246,763 tons, worth $7.08 per ton, respectively; and the gold output from the State totaled $2,480,000.

The Government has enlarged the Royal Commission to go into details of miners' diseases in Western Australia by further appointing Messrs. Montgomery, Mann, Heitmann, and Varden. Presumably, the Commission's investigations will be principally in the direction of ascertaining the best means of minimizing or eradicating the disease. On Dr. Cumpston's finding of 24.5% of dry-treatment hands suffering from early fibrosis, he collected samples of raw and roasted dust, which rose from the ball-mills and furnaces at the Associated Northern. Mr. Larcombe, of the School of Mines, mounted portions for the microscope; and the amount of sharp silica particles in both samples of this dust, which was exceedingly fine, was astonishing. Of course, dust produced by machine-drills underground is coarse and sharp, and would affect a worker's lungs far quicker than one who inhaled dust in a dry-crushing mill. It is to be hoped that some useful suggestions will emanate from the Commission.

During the month the principal mines reported yields as follows:

Name.	Tons.	Yield.	Profit.	Dividend.
Associated	6,909	$ 51,000	....	....
Associated Northern Blocks	1,466	15,500	....	....

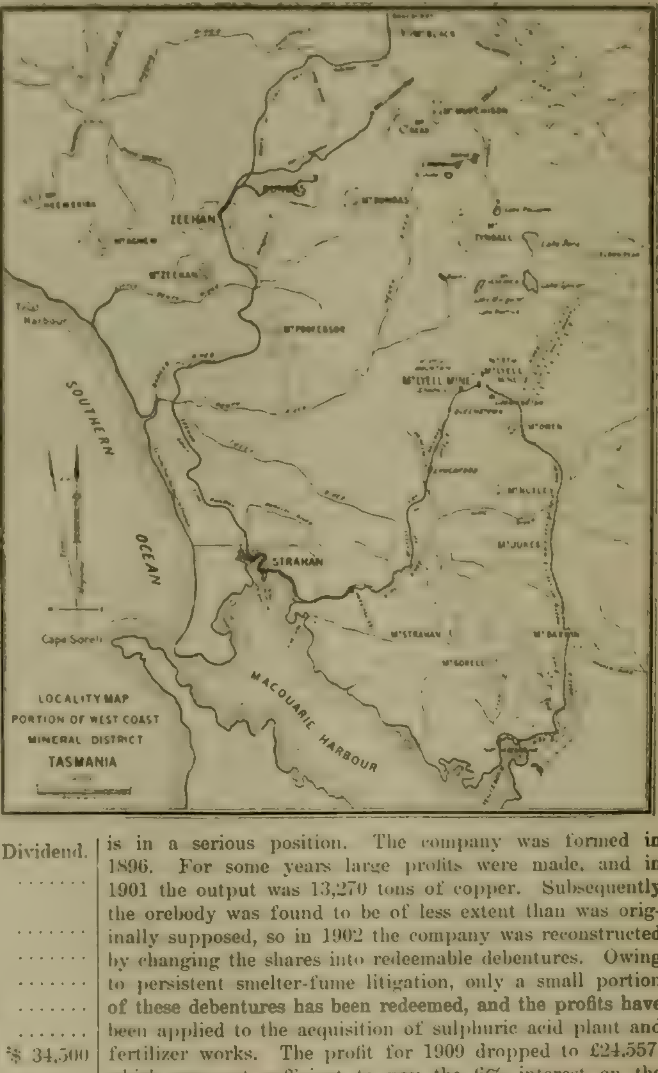
[1] Residue treatment. [2] March.

LONDON

Mountain Copper Co. — Closing of Acid Plant — Zeehan Mines Enterprise — Production for the Year. — Progress at Briseis.

It has always been difficult to obtain exact information either in London or in California about the doings of the Mountain Copper Co., owning mines in Shasta county, and works at Keswick and on San Francisco bay, owing to the policy of secrecy pursued by the Rio Tinto people, who are the London controllers. From the bare statement now issued by the directors it would appear that the company is in a serious position. The company was formed in 1896. For some years large profits were made, and in 1901 the output was 13,270 tons of copper. Subsequently the orebody was found to be of less extent than was originally supposed, so in 1902 the company was reconstructed by changing the shares into redeemable debentures. Owing to persistent smelter-fume litigation, only a small portion of these debentures has been redeemed, and the profits have been applied to the acquisition of sulphuric acid plant and fertilizer works. The profit for 1909 dropped to £24,557, which was not sufficient to pay the 6% interest on the £750,000 of outstanding debentures, while the results for 1910 are a deficit of £3041. This loss is attributed to the fall in the price of copper, the necessity for writing down the value of the stock in hand, the high cost of production, and the unfavorable course of business in California generally. The board has made special enquiries into the state of affairs on the spot, and has in consequence decided to close one of the acid works. C. W. Fielding, who originally introduced the property here, has left the board, and Lewis T. Wright has resigned as manager. People in California are probably better judges of what is to happen to this company than those in London. It is to be hoped that they are more optimistic than the English holders of the debentures.



That adverse circumstances should not be allowed to damp his ardor is one of the prime necessities for a mine manager. A good example is to be found in the case of the Zeehan-Montana silver-lead mine in Tasmania. This mine was floated in London in 1892 as a subsidiary of the Mount Zeehan (Tasmania) Silver-Lead Mines Co., and for many years did well. In 1908, however, all the available ore appeared to have been exhausted, but the manager, John Craze, and the Government geologists were of opinion that further exploration work was warranted, so developments were vigorously carried on. Success rewarded Mr. Craze's efforts and the results have since been encouraging. New orebodies, one with a rich shoot, have been found, and it has been possible to pay a dividend once more, though only a small one, at the rate of 2½% on a capital of £80,000 for the year 1910. During the year 1910, 2908 tons of shipping ore was raised, together with 10,316 tons of concentrating ore averaging 11% lead and 11 oz. silver per ton; of the total marketable product, 2603 tons of ore and concentrate were shipped to Antwerp, averaging 65% lead and 88 oz. silver, and 333 tons was sold to the Tasmanian Smelting Co. averaging 62% lead and 53½ oz. silver per ton. A year ago a tin property was bought cheaply for cash in the adjoining Dundas tin district. Much exploration work has since been done, and it is reported that the lode is large. Unfortunately, though there are rich patches here and there, the average grade is low. Mr. Craze estimates the developed ore at 200,000 tons averaging 0.4% metallic tin, but he doubts its profitableness.

Another Tasmanian mine, the fortunes of which are followed keenly in London, is the Briseis, the tin-gravel property in the northeastern part of the island. It was introduced in England in 1899. Shortly afterward a part share was acquired in the adjoining New Brothers Home No. 1, the Briseis company working the property in return for 58% of the net produce. In 1909, as these properties were approaching exhaustion, the name of the company was changed to the Briseis Tin & General Mining, and gold-gravel properties in Victoria were acquired. In June last the No. 1 property and the southern part of the Briseis were finally exhausted. During 1909 the monthly production was 92 tons of black tin. This fell to 67 tons during the first half of 1910, and to 47 tons during the second half. On December 31 it was estimated that the Briseis still contained enough gravel to yield 45 to 50 tons per month for three years. Work has proceeded steadily with the removal of overburden at the Ringarooma property which was formerly considered unprofitable, but no further information has been obtained relative to the tin content of the underlying gravel. The total production of black tin during 1910 was 684 tons, compared with 1102 tons in 1909, and the corresponding figures for metallic tin were 491 tons and 808 tons. Of the 491 tons, 9 was the share of the No. 1 company, and 428 that of the Briseis. The revenue from the sale was £77,982 or £161 15s. per ton, as compared with £105,953, or £138 per ton, in 1909. As regards the Wallace gold-gravel properties in Victoria, the old dredges are just paying their way with a very small output, and of the two new dredges one is already at work and the other should be ready shortly. During 1910 the company made a profit of £32,125 and distributed £30,000 as dividend.

JOPLIN, MISSOURI

Miami, Okla., Camp Takes New Lease on Life.—How Water Problems are Overcome.—Back to the Soft-Ground Mines at Duenweg.—Big Production from Small Plants.—Notes of the Zinc and Lead Mines.

A deeper and richer formation, almost exclusively zinc-blende, has been discovered in a drill-hole put down by the Miami Royalty Co. on its lease of the Wat-tah-no-zhe land. While previous operations have been confined to the zone lying between 100 and 130 ft. deep, the new strike is at a depth of 204 to 231 ft., and an assay of the clippings shows the blende content to be almost 50%. One mile north of Miami the L. C. Church Mining Co. made a similar find last year and a shaft has been sunk to the ore; but this was thought merely a continuation of the shallow ores of the main camp, which dip to the north. But the new drill discovery shows the ore to be a separate formation. Not only is the dirt rich in ore, but the quality of the blende is much higher than that found in the shallower deposits. The zinc content of the cleaned blende will be 60 to 61%, while in the shallower deposits a high percentage of iron pyrite is found, for which a deduction of $1 per unit is made. The Miami Royalty Co. will sink a shaft at once to the deep run.

The Little Jewel mine, west of Joplin, originally faced a serious pumping problem, the flow being so heavy the pumps could scarcely handle it, but when the Chicago-Joplin mine, 1000 ft. to the south, started work on a deeper level, all the water was drained from the Little Jewel, and it is now pumping water for its mill use from the abandoned Mandarin mine, on the Riseling land, 2000 ft. to the west. The water is taken from a depth of 180 ft., is pumped into a 35-bbl. tank on a tailing heap, 40 ft. above the ground, and from there flows by gravity to the sludge-pond of the Little Jewel. The company has driven around caved ground and gone into good blende at a depth of 140 ft. Heavy timbering was required to keep the loose dirt from coming in.

In the Duenweg camp, operators are showing a tendency to return to the early methods of mining, and the rush of prospectors is back to the tracts where the shallow ores are found. Turn-ins may not be quite so large from the soft-ground mines, but the margin of profit will be decidedly greater. Lead ore is again being taken from the old Log Cabin land, the new lessees, Martin & Co., having taken from old drifts more than 2,000,000 lb. of free lead in the past few weeks, and in their new ground rich pockets of galena are being found. Three sub-leasing companies are also hard at work, and in two instances, where shafts have been put down beneath the lead, which occurs at 100 ft., good blende is found. Hand-jigs, horse or steam hoists, and in one instance a hand windlass, complete the crude equipment requisite for the successful handling of the ores.

In 'Possum Hollow, at Chitwood, northwest of Joplin, similar conditions prevail, and deeper operations are being conducted on the Granby land. Mines which have long been idle are once again in the production lists. The Jack 'Possum mine is being developed at a depth of 126 ft., the dirt, which is treated on three hand-jigs, running 15% blende and lead. From these three hand-jigs a production of 60,000 lb. of blende and 2000 lb. of lead is being made weekly. It will be necessary to install crusher and rolls, as some of the material is 'chatty' and cannot be treated on the hand-jigs without being pulverized. Clarke Marshall, James Roller, and Newt Doty are operators of the mine.

Modern pumping equipment has solved a difficult problem in the Zincite camp, west of Joplin, where successful operations are being conducted by the Urbana Mining Co. An 8-in. centrifugal pump is kept going continuously night and day, to drain the workings of this single mine. The ore occurs in muck at a depth of 145 ft. Near this mine the old Keystone property was worked a number of years ago, but was forced to close down because of the heavy water. Hand-jigs have been installed to clean the output.

The stockholders of the Falls City Lead & Zinc Co. have rebuilt a plant which burned down recently, and operations have been resumed. The 500-ton mill is of galvanized iron, and as nearly fireproof as possible. The mine is on a 26-acre lease of the Liberty Mining Co. Two shafts are into ore, the pay-dirt being found in one shaft at 165 ft. and extending down to 200 ft., while in the other shaft it is found at 180 ft. and continues down to 225 feet.

A prospect drill is at work at the Wilcox mines at Chitwood, perched high on top of the John Jackson tailing pile that was turned out from the district's most famous mining plant. The tailing pile, which covers more than an acre, lies directly above a tract of land that has never been mined nor drilled. To determine the nature of the ground beneath this heap it was necessary to sink the drill-hole directly through the pile. In spite of this, little difficulty has been experienced.

GOLDFIELD, NEVADA

June Production of Goldfield Cons.—Concentration Discontinued at Florence Goldfield Mill.—Less Working Costs.—Progress on the Polverde.—Progress Notes.

Preliminary estimates of production of the Consolidated Mines Co. in June, obtained from the general superintendent, J. F. Thorn, place the gold recovery, after allowing for all metallurgical losses, at $880,000, from 28,540 tons, or an average of over 950 tons daily, or $30.84 per ton. Total operating costs were $230,000 and net profits approximately $650,000. The superintendent reports that the mines are in excellent condition in all departments. Both the Consolidated and Florence companies advanced their monthly pay-days and paid their employees on the third, in order that they might celebrate the Fourth and attend the aviation meet, participated in by two professionals, with monoplane and biplane, and the first exhibition of birdmen to be given in a mining camp. The greater part of the hoisting is accomplished on the day shift, and the mines, with the exception of the Clermont, are practically closed on Sundays. Another shipment of bullion was made late last month, the value of the 12 gold bars being $300,000, the bullion being above 900 fine.

FLORENCE GOLDFIELD MILL.

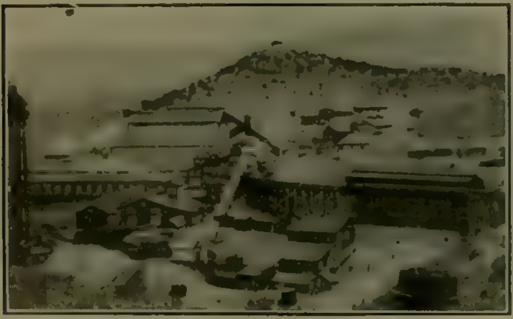
Further economies in the cost of ore treatment are being effected by the Florence Goldfield company as a result of changes that have been made in the processes employed in the mill. Hereafter the milling will be confined to amalgamation and cyanidation. The resulting improvement has been demonstrated by Willett Barton, superintendent of the mill. Additional equipment has been provided at a cost of about $1600, and it is estimated that $25 per day will be saved in labor alone. One part of the equipment consists of an Akins classifier and a Dorr pulp thickener, and the intention is to dispense with the use of the Deister tables, Frue vanners, Callow classifiers, and a number of settling-tanks; thus the necessity for much of the elevating and pumping heretofore done will be eliminated. Upon leaving the stamp batteries the ore will pass over amalgamated plates to the Akins classifier, the fine being diverted to the Dorr thickener, and the oversize to the tube-mills, the entire product being carried finally to the cyanide tanks after the reground ore has been returned to and has passed over the amalgamated plates. Lately the mill has been treating 160 tons daily, the total cost having been reduced to a little less than $5 per ton. This process of treatment is expected to raise materially the percentage of gold recovery, which has varied in the past from 93 to 95%. The plant is being operated in an economical manner, and at a cost per ton of ore lower than that achieved by any company operating in this part of the State. The results of operations under the management of Willis Lawrence have been gratifying, as the losses in mill work are much less than had been anticipated before the mill was built. The main shaft is being sunk without interruption and has reached a depth of nearly 800 ft. A station has been cut at the 800-ft. level, and from it lateral work will begin at once. Drifts and cross-cuts are being driven to the east, north, and south from the 400 and 650-ft. stations, and ore of excellent grade is being broken in new workings on the 500-ft. level and on the 750-ft. level in the Reilly ore-shoot, at the northern extremity of the Florence claim. The ore now exposed in the mine is probably sufficient to supply the mill.

On the Polverde claim of the Jumbo Extension Co. some good ore has been opened in the new drift on the 600-ft. level where a station has lately been cut. In the company workings on the 1030-ft. level a change in the formation is apparent, which affords ground for the belief that the main vein is being approached. The Annex company, which has been operating a lease on the central part of the Polverde claim, has shipped much ore from the 760, 800, and 850-ft. levels, will soon resume work on a larger scale, according to recent advices from the Eastern heads of the company. This company has expended about $100,000 in development. On the Spearhead, lessees are now raising from the cross-cut on the 300-ft. level to reach the orebody exposed on the 250-ft. level. A lot of tailing from the old Kinkead mill, near the foot of Columbia mountain, is being treated by cyaniding at the chlorination mill, north of town. The Sandstorm-Kendall is developing from the old Kendall shaft and has some fairly good ore on hand. Lessees on the Sandstorm are saving some shipping ore. Another lease has begun work on the Hat claim of the Blue Bull. Three lessees are working on the claims of the C. O. D. Consolidated, in addition to the work of the company, from the 600-ft. Sills shaft.

MEXICO

Mexican Eagle Oil Co.—Semi-official Character of Pearson Company.—Relations with Standard Oil.—Cost of Production at Cananea.—Profits for Year.

The Mexican Eagle Oil Co., the marketing concern of the Pearson oil interests, which has been warring with the Waters-Pierce Oil Co. (Standard Oil) for control of the Mexican field, is at present in the limelight, due to an unofficial investigation started by the Maderos. It is a matter of common knowledge that the Pearson interests, of which Lord Cowdray, formerly Sir Weetman Pearson, is the head, were very close to the Diaz government, and were paid many millions for the rebuilding of the Tehuantepec National railroad and the construction of harbor works at the isthmian ports of Coatzacoalcos and Salina Cruz. When they decided to engage in oil exploration and development in Mexico they were granted valuable concessions by the Diaz administration. In 1908 the Pearsons started the sale of oils in competition with the Waters-Pierce company, and the following year the Mexican Eagle Oil Co. was organized to take over some of the Pearson oil lands and concessions and to handle the marketing of the Pearson products. Guillermo Landa y Escandon, then governor of the Federal District, was elected president of the new company, and Enrique C. Creel, the former minister of foreign affairs, and Lieut.-Col. Porfirio Diaz, son of the president, were among those who joined him in the directorate. Since the organization of the Mexican Eagle company a strong fight has been made for control of the oil market in Mexico, and the Mexican concern now is credited with having about 40% of the business. The fact that men prominently connected with the Diaz administration appeared as the principal figures in the new company gave it something of an official character, and their participation is responsible for the present inquiries into its affairs. What is alleged to be a photographic copy of the minutes of a meeting held April 11, 1910, showing the free distribution of 1333 preferred shares, par value ₱1000, among the men forming the directorate, has been published. However, denial that the shares were free has been made by several directors. An inspection of the Pearson and Mexican Eagle holdings has been made by officials of the Texas Oil Co. and the Gulf Refining Co., and this has started the report that the Pearsons contemplate selling out to Standard interests. In an interview, J. B. Body, head of the Pearson interests in Mexico, stated that the inspection was with the object of determining the probable productiveness of the Pearson fields, but not with a view to the purchase of the properties. It is intimated that the American interests plan to purchase crude oil in Mexico for shipment to the United States. Mr. Body denies that the concessions granted the Pearsons are monopolistic in character, stating that they do not differ materially from those granted other oil interests. He declares that the Standard interests are using the press in an attempt to injure the Pearsons. In connection with the publicity being given the Pearson affairs, the report that the Standard Oil gave financial aid to the Madero revolution has been recalled. A formal denial of this report was made some time ago by the Standard Oil Co., and Francisco I. Madero has taken occasion to deny it several times.



GREENE-CANANEA CONCENTRATOR.

The 1910 report of the Greene-Cananea Copper Co. shows that the cost of producing copper at Cananea, not counting construction, was 9.66c. per pound. Construction charges increased this to 11.51c., as against 11.64c. in 1909. The last of the heavy expenditures called for by the company's extensive program of betterments has been made, and during the remainder of this year it is expected to produce copper at 9c. or less per pound. The average price received for Cananea copper in 1910 was 12.62c. per pound. The total copper produced in the year was 45,680,145 lb., and the total revenue $5,592,050. The deduction of total expenditures of $4,407,301 left an operating surplus for the year of $1,184,749, and this was reduced to a net profit of $459,202 by construction charges of $684,097, and a profit and loss charge of $41,451. The average recovery from domestic ores was 2.32% copper and 1.03 oz. silver, as against 2.206% copper and 0.75 oz. of silver in 1909. The report shows a saving of $5000 monthly as a result of the use of fuel oil.

MIAMI, ARIZONA

PROGRESS AT THE MIAMI.—INSPIRATION POWER-PLANT.—RECORD WORK AT LIVE OAK SHAFT.—REOPENING OF NEW KEYSTONE.—PROSPECTING THE ARIZONA COMMERCIAL.

The Miami Copper Co. is now producing about 65 tons of concentrate per day. The grade of the concentrate is still about 40%, and the mill saving remains at or slightly above 75%. Unit No. 4 has been under test for a few weeks, but propably will not be operating at its full capacity until certain minor portions of its equipment have been changed. The bearings of the rolls are being altered in order to make them detachable when repairs are necessary. It is not yet definitely known when units No. 5 and 6 will begin operations. A tramway leading up the hill from the railway terminus at Miami to the mining and reduction plant on the hill has been in operation for several days and will convey all supplies formerly moved by wagons. The power-house is receiving its final test, Frank Zlatink and Louis Lenz, of the Nordberg company, being here for that purpose. Thus far the machinery of the power-plant has been satisfactory. The timber that will be interposed between the orebody and the overburden is being put in place as fast as miners open the ground.

The Inspiration power-plant, consisting mainly of a generator and a Ball high-speed engine to operate it, is almost installed, and much of the surface and underground machinery has arrived. The main haulage level has been laid with heavy track and that section of it connecting the Jo Bush and Colorado shafts has been widened. The drills have been meeting with uniform success. At 600 ft. northeast of the Jo Bush shaft a drill recently found 100 ft. of 2.8% ore, and 2.4% ore was cut in a hole 600 ft. north and 300 ft. east of the same shaft. Underground work at present is confined to development, and the force probably will not be increased until the site and date of beginning of the mill is decided on. It still seems uncertain whether the latter will be erected at Wheatfields, 11 miles below the mine, or some point upon the property. W. H. Aldridge, managing director, has said that the Miami people have made an offer to share the ownership of their reduction works and power-plant with the Inspiration, and that the latter suggested consolidation of properties. No agreement having been reached, he says that the Inspiration will immediately proceed to build a 5000-ton mill. Live Oak shaft No. 2 is now more than 400 ft. deep. The sinking of this shaft has been a record-breaking performance, one month's work breaking the former world's record. Moreover, it was sunk 12 ft. in one day. Oil burners have been substituted for the coal formerly used. Three churn-drills are operating near the southwestern corner of the property. At the old shaft considerable work in the nature of preliminary steps to blocking out are under way at the old shaft (No. 1) at the 445-ft. level. A telephone system connecting the various portions of the property's workings with the main office has been installed. A new office building is being erected. The New Keystone will begin work soon, the last meeting of the directors at New York having resulted in an agreement to open the property again. It contains about 2,000,000 tons of developed and partly developed ore, which is 400 ft. above the Miami mill, so that it can be conveyed to the concentrator by an aerial tramway.

Superior & Boston has now driven the southwest drift from the McGaw shaft on the 1000-ft. level about 160 ft. along the foot-wall of the Great Eastern vein and is still in ore. The vein has not yet been cross-cut to ascertain its breadth, but where the drift crossed the vein at their point of contact near the shaft it seemed about 18 to 20 ft. wide. The ore is chalcopyrite, contains glance, and has a heavy iron content. It is better than the ore found in higher levels, in that it is less silicious. Although of obvious value its worth will not be known until after a smelter run. Some of it must soon be smelted, for the ore taken out of the drift is already crowding the capacity of the bins. The Arizona Commercial's Eureka shaft is now 1000 ft. deep. Just below the 1000-ft. level the diabase altered to a more broken formation. Driving along the foot-wall of the Black Hawk vein on the Great Eastern vein and cross-cutting shows the vein to be about 40 ft. wide. Whether the Black Hawk vein will yield much ore of commercial value will not be known until it has been more completely developed. The cross-cut being driven north at the 1000-ft. level to cut the Old Dominion fault is being pushed forward at an even gait through the quartzite that lies north of the Black Hawk vein. In the Superior & Boston (adjoining the Arizona Commercial on the east) a cross-cut being driven at the same depth to cut the Old Dominion fault is now supposed to be near the fault (vein) and is in broken quartzite heavily stained with iron, but neither of the companies knows just how far it must be driven to reach it, as its dip at this point has not heretofore been ascertained. The Summit Copper Co. is confining its operations now to development work solely. The parallel Pasquale and Summit veins each have been explored a distance of 1500 ft. from north to south. The rich chalcopyrite ore that has characterized the work on the Pasquale vein still obtains. In the depth from the 200 to the 400 the central streak of 30% chalcopyrite widened from 10 in. to a shoot that varies from 2 to 4 ft., and the 400 drift south is still in good ore at 460 ft. from the shaft.

NEW YORK

Dullness of Market. Denial of Injunction. Live Oak Issue. Ray Central Merger. Gold Roads Sale. Lead Ore Contracts. Wettlaufer Dividend. Railroad at Porcupine. Exaggerated Claims.

The market for the week has been of a distinctly preholiday character with a steady daily decline in the volume of business, as traders prepared for absence over the week-end, to celebrate Independence Day. A more contradictory, leaderless market could hardly be imagined. The dismissal of the Government's suit to dissolve the Harriman merger was made much of as an item of good news, and was immediately followed by the indictment by the Federal Grand Jury of the leading factors in some of the United States Steel wire pools. It is probable that every Government move from this time forward will have political significance, but, on the other hand, the corporations and combinations, and the people at large, refuse to give way to any less disagreeable question.

Coppers are the leaders of the New York and Boston mining-share market, and there is not enough in the slightly improved condition of the metal to induce any increase in activity in the leading issues. Favorable annual reports and statements of improved conditions, as in the case of Greene-Cananea and Giroux, had no perceptible effect. Judge Swan of the United States Supreme Court in Michigan, has rendered a decision denying the injunction asked for by G. M. Hyams to prevent the Calumet & Hecla merger. While this suit was the most important one in Michigan, there are other suits pending in that and other jurisdictions, so that the Lake merger is likely to be long delayed. The Live Oak Copper Mining & Smelting Co. is to issue 31,250 shares of stock at $20 per share. Stockholders have the right to subscribe on the basis of one share of stock for each two now held. Live Oak, Inspiration, and Miami will probably amalgamate when the Live Oak gets ready to begin production. The engineers are busy with the Ray Central-Arizona Hercules merger. Frank H. Probert left New York this week for Kelvin in connection with the work. The long-pending suit of some of the minority holders in the Greene Consolidated Copper Co. for an accounting has been dismissed. The suit was in the nature of a bill of discovery, and an examination of the officers of the Greene Consolidated, had before trial, evidently convinced the attacking parties that they could not make out a case, and dismissal followed.

The purchase of the Gold Roads property, at Kingman, Arizona, by the United States Smelting, Refining & Mining Co. has just been completed in Paris. The examinations were made by Sidney J. Jennings of the Smelting company's regular staff, and Ferdinand Robellaz, a prominent mining engineer of France. The price paid for the property is announced to be $1,435,000. Mr. Jennings' estimate of the ore reserves was $2,700,000 gross, with $700,000 net in the developed reserve. The estimated tonnage was 300,000, of which one-third is broken in the stopes; average value, $9 per ton. The Tonopah-Belmont Development Co. is to hold a special stockholders' meeting, July 15, to vote on the question of reducing the capital stock of the company from $2,000,000 to $1,500,000, by canceling the quarter of a million of unissued stock in the treasury. The step is recommended by the directors to avoid taxation.

The Chino Copper Co. shareholders have ratified the $2,400,000 bond issue and Chino is now active in the open market. The public takes a great deal of interest in convertible mining bonds, and the standard issues, such as Braden, Miami, Ray Consolidated, Utah Copper, and Mason Valley, all sell above par, at figures ranging from 105 to 125. Some of the original holders of the Nevada Consolidated bonds made very handsome profits through conversion of the bonds into stock. A recent report on the Inspiration gives the ore reserve at 24,403,500 tons, averaging better than 2% copper. Among the lead contracts recently secured by the International Smelting & Refining Co. is that of Coeur d'Alene North Fork Mining & Smelting Co., whereby the Tooele smelter will handle all of the output of the Monarch mine, east of Murray, Idaho. The property is expected to provide 900 tons of lead concentrate monthly, running about 55% in lead with some silver.

The Wettlaufer Lorrain is claiming a place as a regular dividend payer, having just declared its second quarterly dividend of 2½% of regular and 2½ of extra. Wettlaufer is said to be much stronger in ore reserves than the average of the Cobalt dividend payers. Fred Hellmann, of Leggett & Hellmann, recently appointed consulting engineer, is now at the property in active charge of the development and operations of the mine. The railroad into Porcupine from Kelso is said to have cost $2,000,000. An extension of 3½ miles from the southern end of Porcupine lake across to the Hollinger mine is to be immediately built and will be financed by a loan of $150,000 to the railroad commission by the Hollinger company at 5%; principal to be repaid by the Hollinger in paying 30% of its freight bills in cash and 70% being applied to the reduction of the loan. The extension will give transportation to some of the very important properties of the district, including the Dome, North Dome, and the Dome Extension.

CHINO CONCENTRATOR FROM TOP OF POWER-HOUSE.

Henry Krumb, one of the best known engineers of the country, is inclined to take a very conservative view of Porcupine. Referring to some of the ridiculous values placed on raw claims, he says: "Forty acres in the swamp is valued at $100,000, which figure is doubled if a quartz outcrop can be found, $50,000 added if a speck of free gold is located, and thereafter the price advances $50,000 per speck." This is sarcastic, but not without some foundation in fact. Porcupine has been without the publicity required to make a boom mining camp, and the interests centred there are turning to means other than the press to get the possibilities of the district before the people. The latter part of July is to see some large excursions into the new goldfield. Plans are being perfected to carry 800 Chicago people to Porcupine by special train, to be followed later by 200 more from Detroit and Cleveland. If there is not a world of business in the gold-mining shares of the new camp, it will not be for lack of exchanges. Toronto has two now, and a third one, organized by New York Curb brokers and ex-Goldfield, Nevada, promoters, is to open on July 15. It is not improbable, however, that Porcupine will eventually be demonstrated to be a camp of large low-grade producers, with little of the highly speculative features so earnestly desired by boomers, promoters, and share brokers.

General Mining News

ALASKA

Copper River

Shipments of ore from the Bonanza mine over the Copper River & Northwestern railroad to Cordova amount to about 350 tons per week. This is ore of high grade, which is shipped thence to the smelter at Tacoma.

Juneau District

The report of the Alaska United Gold M. Co., for the month ended May 15, 1911, shows that its two 100-stamp mills operated practically full time; that there was crushed in the two mills 35,323 tons of ore, and 743 tons of concentrate was saved. The estimated gross value of free gold recovered in both mills was $40,158; estimated gross value of concentrate, $35,907; total, $76,066. Estimated realizable value of product, $75,343. Operating expenses, $55,136; operating profit, $20,212. Construction expenses, $6375. Yield of ore milled, $2.41 at Ready Bullion mill, and $1.84 at 700-Ft. Claim mill. Development work consisted of 432 ft. on Ready Bullion, and 593 ft. on 700-Ft. Claim mine.

Prince William Sound

The Beatson mine, situated at Latouche, is owned by the Beatson Copper Co., for which Stephen Birch of New York is president and general manager. W. H. Seagrave is in direct charge. The property was located in 1897 by A. K. Beatson and five associates. Regular mining operations were commenced by Mr. Beatson in 1901, after he had bought the interests of his associates. In the purchase of those interests, patenting the 17 claims, developing, and building there was expended $105,981, besides work done with profits from the mine. Up to 1910 all of the business relating to the property was done in the name of A. K. Beatson. After June 1904 the proceeds of ore shipped to Tacoma more than paid expenses. In May 1907 profits amounting to $50,000 were divided, and there was another dividend of $65,000 in January 1908. During 1909 there was shipped 5092 tons of ore, from which was produced 1,264,053 lb. copper and 8820 oz. silver. The net profit for that year was $53,713, or 4½c. per pound of copper. As the price of copper that year averaged 13c., the cost of production was 8¾c. per pound, and included in this expense was the cost of 1051 ft. of development work. Soon after the mine was purchased by the Guggenheims in 1910, the latter incorporated the Beatson Copper Co., to which the property was transferred in June of that year, when Mr. Beatson turned over the management to Mr. Seagrave. It is understood that this year shipments are being increased as transportation facilities can be obtained.

ARIZONA

Gila County

(Special Correspondence.)—The Southwestern Development Co. is the name of a new organization that has bonded four claims adjoining the Live Oak group. They will soon have a churn-drill operating on the property. The company is composed of New York and Boston capitalists, probably brokers. They have issued a statement to the effect that the stock issue has already been oversubscribed. The German Copper Co., formerly the Arizona Colorado Copper Belt & Gold Mining & Milling Co., is driving on the 800-ft. level. The mine superintendent, Sell Tar, reports favorable indications to date. The property is 2½ miles north of Globe and formerly was the scene of much activity.

Miami, July 3.

Yuma County

(Special Correspondence.)—The 700-ton smelting furnace of the Clara Con. Gold & Copper Mining Co. was blown-in on June 19. Some construction work in the way of improving facilities for handling and treating ores is still going on. A spur track from the Arizona & Swansea railroad is being extended by means of a switch-back to a point above the reduction works, which will allow custom ores, coke, and fuel to be handled by gravity direct to the points of consumption at a minimum cost. A No. 11 Roots blower is being put in position which will give additional blast to the furnace and considerably increase its capacity. A 44-ft. structural-steel extension to the converter building has recently been completed. The sampling plant for handling custom ores has been finished and is now in operation. This will give the small producers of this section an opportunity of disposing of their ores, and will, no doubt, greatly increase mining activity in this vicinity. Development of orebodies in the company's mines at Swansea is being pushed, particularly on the 400 and 500-ft. levels. Considerable exploration work with churn-drills is also being conducted with good results.

Swansea, July 1.

CALIFORNIA

Amador County

Work was started on the Amador Queen mine in Hunt's gulch, adjoining the Doyle mine, south of Jackson, last week. A shaft was sunk on the property some years ago to a depth of 1000 ft., when it was owned by an English company. It is proposed to reopen the mine and give the ground a thorough prospecting. It is confidently believed that a pay-shoot exists within the boundaries of the claim.

Butte County

(Special Correspondence.)—The Granite Basin Mining & Milling Co., at Buck Ranch, Butte county, has begun operations on a large scale to open the tunnel and block out ore. The mine was proved in former days, and the present owners will extend the work commenced by the old-timers. Twenty men have been put to work during the month. E. A. Robinson is superintendent. George E. Sparks and A. Lawton have started development on their quartz and gravel drift mines at Lumkin, with a view to proving the amount of ore available before figuring on the building of a mill. The work is in charge of E. R. Sears. The Phoenix Mining Co. of Hurldon is sinking on its lode, on which good ore has been found. H. W. Latimer and associates of Los Angeles are owners, for whom R. Kellett is in charge. A number of miners are employed at the Enterprise mine, at Enterprise, sinking on the vein. This property was formerly owned by E. E. Burke of Santa Rosa. Clark and Bohaman of Oroville have opened a vein of gold-bearing quartz. Their claims are about 3 miles from town on the west branch of the Feather river.

Oroville, July 1.

Inyo County

A serious cave-in caused a temporary suspension of operations at the property of the Golden Star Mines Co., in the Argus mountains. Sixty-five men have been at work, the daily output being about 80 tons of ore, which is treated in a cyanide plant. While cleaning out an old shaft on the King Solomon, Frank Buys discovered a seam of ore dipping into the hanging wall. The new discovery is on the 100-ft. level and is 12 in. wide. Preparations are being made to sink the shaft. The Keane Wonder mine, in the Death Valley district, has been bonded to George Wingfield, of Goldfield, Nevada. Investigations are in progress.

Nevada County

The Champion group of mines near Nevada City, a famous group that has produced some twenty million dollars in past years, was sold recently to J. M. O'Brien of San Francisco. Six months ago Mr. O'Brien took an option on the property, and has had 20 men at work exploring the property. The workings are now down 2400 ft. on the incline, and it is probable that a central shaft will be sunk, and nearly a half million dollars will be spent on new equipment. Recent statements to the effect that this mine has been taken over by the North Star Mines are incorrect, but it is not impossible that the control of this group will finally be acquired by the North Star Mines. Recently the mine has been working 60 men on production and 20 on development work. There is a 20-stamp mill on the property. The Delhi mine has temporarily suspended operations, due to a scarcity of water. A good record for shaft sinking was made [illegible] by the six men who are sinking the new shaft [illegible]. A depth of 40 ft. was obtained in [illegible] days. The shaft is a

MILL AT CHAMPION MINES.

compartment one and is 18 ft. long and 10 ft. wide. A hoist and skips are to be installed soon and even a better record is then expected.

SHASTA COUNTY

Three furnaces have been banked at the Mammoth smelter to allow a rearrangement of the cooling-pipes leading to the bag-house. The present number of pipes is the minimum possible for operation of the furnaces. More pipes have been added, and the series rearranged so that the temperature can be materially reduced. The life of the bags under present working conditions is very satisfactory. At the Balaklala, experimental work is still in progress to perfect the method of removing dust from the smelter fume.

Work on one of the greatest power development projects in the State, if not in the West, is going on quietly in the Big Bend of Pit river, near the towns of Wengler and Henderson. One quarter of a mile of heading is completed. The tunnel when finished will be nearly seven miles in length. The Mt. Shasta Power Co. is the corporation that has the project in hand. H. V. Gates, residing at Hillsborough, Ore., who is interested in half a dozen or more power companies in Oregon and Idaho, is the moving spirit. R. E. Johnson is the chief engineer. Several years ago 150,000 in. of water in Pit river was located. The surveys are practically completed and crews of men are working at each end of the 7-mile tunnel. Machine-drills are used and the tunnel is driven 150 ft. per month.

SIERRA COUNTY

Henry Goering is reported to have made a find of rich nuggets at the Haskell Peak mine.

Good progress is being made at the Tightner mine. The machinery for the 10-stamp mill is being shipped to the property and the 4-drill compressor is now running. C. C. Derby and L. N. Wagner, of Nevada City, are superintending the construction and development work for J. M. O'Brien, who recently took up the option on the property. H. L. Johnson, the owner, has taken out, it is stated, a million dollars from the upper workings on the vein. The adit recently driven on the 1400-ft. level has cut the ore-shoot where it is equally as good as above. This gives 650 ft. of new ground, and some $100,000 worth of ore has been taken out of the adit during development work.

YUBA COUNTY

J. P. Lyon, Robert Buckley, and Russell Wright, of Vacaville, have taken a lease on a piece of placer property near Comptonville and plan to start working it next month.

COLORADO

The total production of gold in Colorado up to December 31, 1910, is estimated at $487,491,998. The production of gold in Colorado during 1910 was $20,297,535.

CLEAR CREEK COUNTY

(Special Correspondence.)—A body of ore 5 ft. wide was opened last week on the eleventh level of the Gem mine, 800 ft. east of the main shaft. A shipment of 100 tons of ore from this mine brought [illegible], making the average value [illegible] per ton. A. H. [illegible] & Co. are operating the mine as lessees. The East [illegible] M. Co. has been incorporated to operate the [illegible] mine. [illegible] is manager. The operations will be carried on through the Central adit. The Seaton Mountain E. Co. has a contract to furnish the Big Five M. Co. with power for its transportation system. The Centennial mine of the Two Kings G. M. Co. is to be provided with a 60-hp. boiler, 30-hp. hoist, and a Blaisdell 5-drill air-compressor. At the annual meeting of the Hoosac T. & M. Co. the board of directors was re-elected. E. D. Quigley will remain as manager.

Idaho Springs, June 27.

(Special Correspondence.)—Development has been put under way on the Baker mine, situated on Kelso mountain. A cross-cut has been started to get the ore below the upper workings. Coggswell brothers are operating under a lease. The Clinton M. Co., controlling property on Wood mountain, has purchased an air-compressor, which is now being placed in position. It is proposed to extend the adit 4000 ft. A carload of galena ore was shipped last week from the East Griffith mine to the smelter at Salida. The ore sampled $45 per ton in silver and lead. Ericson & Co. are operating the property as lessees. Work is to be resumed in driving the Vidler adit through Argentine pass. It has been decided to drive from the west side.

Georgetown, June 26.

GUNNISON COUNTY

It is reported that molybdenite in large quantities has been discovered near Crested Butte. Molybdenite is used in the manufacture of molybdenum steel. The sale of the old Walrod properties on Cement creek to Boston interests is reported. F. Austin Wilson has started work on the Washington mine, at Irwin, and has a gang busy repairing the pumping plant. As soon as the wagon-road to the Sapp mines is in shape, ten 4-horse teams will start hauling ore to the railroad. It is expected that a post-office will be established at the mine soon.

LAKE COUNTY (LEADVILLE)

Exploratory work during the last six months has resulted in the finding of zinc, lead, and iron ores, often in places where it was supposed that the ores had long since been extracted. The output from the Yak tunnel is greater than for years past; 25 sets of lessees are now at work, and most of them are shipping. The Valley shaft, the Little Jonny, and the Garbutt are notable producers. The Siwatch adit is expected to cut the first of the veins it was driven to intersect in the near future. At the Helena, in Iowa gulch, a good vein of lead ore has been found. Now that the snow is gone from the higher mountains, results may be expected from prospecting work.

OURAY COUNTY

It is expected that the Humboldt mine will be sold to French interests, as Fred G. Farish, representing the owners, and Hy Knoertzer and L. Chevrillon, for the purchasers, have just made an examination of the property. The property was sampled last fall, and the present visit was merely to check the previous work. The rumor that $50 ore had been cut by a diamond-drill in the workings of the Camp Bird proves to have been without foundation. The Altoona, Ruby Trust, and Yankee Boy have recently been examined in the interest of Philadelphia investors, and the report is said to have been favorable. G. H. Barnhardt has resigned as manager of the Wanakah Mining Co., and J. T. Roberts, Jr., is now manager. The company has 40 men at work.

SAN JUAN COUNTY

(Special Correspondence.)—The Silver Lake mine has been opened on company account, and 15 men started breaking ore June 20. It was persistently claimed by the agents of the Garfield Smelting Co., owner of the property, that work would not be resumed on company account, so that the present operations come as a decided surprise to this district. It is hoped that the work will be carried on as outlined. The plan is to start on a small scale and mine the ore in sight, starting the mill at the end of 30 days. If the result of this month's work is encouraging, development will be started and an effort made to bring the property back to the normal tonnage of 300 tons per day. The property has been idle since 1908, except for small leases, and the announcement that the company intends to restore this mine to its old position as the largest producer of the district is welcome news. The Highland Mary mine has been leased to George Hill and Dan McLean, well known local operators, and the lessees announce that mining will start at once. This mine has produced some good ore, and will, no doubt, again join the shippers. Several smaller leases are reported, but none have begun work. The owners of the King mine are in Silverton, and plans are being completed for the operation of this property, which has shipped large amounts of crude lead and zinc ore.

Silverton, June 24.

TELLER COUNTY (CRIPPLE CREEK)

The June production of the Cripple Creek mines was 76,798 tons, of an average value of $17.82 per ton, corresponding to a gross content of $1,355,040. The low average per ton is due to the large amount of low-grade ore now being treated. The Isabella mill, operated by the Western Reduction Co., is treating old tailing, and the average recovery is given as $1.20 per ton. The ore from the Stratton's Independence dump also shows a slight decrease in grade. The figures as to the ore treated at the principal mills and smelters during the month are given below:

	Tons.	Average Value.	Gross Bullion Value.
Colorado City—			
Golden Cycle	26,000	$20.00	$520,000
U. S. R. & R.	13,815	22.00	303,930
Portland	9,800	21.50	210,700
Cripple Creek—			
Portland	8,770	3.00	26,310
Stratton's Independence..	10,500	2.74	28,770
Isabella	3,900	1.20	4,680
Smelters—			
Denver and Pueblo......	4,010	65.00	260,650
Totals	76,795	$17.828	$1,355,040

The figures for July will probably show an increase, as the Little Giant mill in Pony gulch is expected to begin work, and the Wild Horse will resume operation, having been remodeled. The Blue Bird mill was closed during June. Good ore has recently been found on three properties, the Laura Lee on Mineral hill, the Conundrum, and the Gold Sovereign on Gold hill.

IDAHO

SHOSHONE COUNTY

The Coeur d'Alene North Fork M. & S. Co., owner and operator of the Monarch mine and mill on Pritchard creek, near Murray, has arranged to ship its lead-silver concentrate to the Tooele plant of the International Smelting & Refining Co., and its zinc concentrate to an Oklahoma smelter. Now that its Monarch mill has been increased in capacity to 200 tons per day the company probably will be able to ship 900 tons of concentrate per month to Tooele. This product is expected to sample 55 to 60% lead, and 10 to 12 oz. silver per ton; the zinc concentrate will probably amount to 100 tons per month, and this will carry 45 to 50% zinc, 3 to 5% lead, and 10 to 12 oz. silver per ton. As has been noted before, the Monarch mine's lowest level consists of a 3200-ft. cross-cut that taps the vein at a vertical depth of 1400 ft. It is now announced by E. P. Spalding, the manager, that sinking is to be commenced this month on the ore-shoot where it is exposed on the lowest level. This shoot has a length of 300 ft. and a width of 3 to 16 ft. The great vein is opened from the 1400-ft. level to the surface by raises and shafts.

The Paragon Con. M. Co., having extensive holdings on Paragon gulch, above the Monarch, has been developing at two places on its group, and has exposed considerable of galena and zinc ore, the shipment of which has been commenced. The first car of ore was shipped to Salt Lake City last month. L. W. Steadman, of Murray, is manager.

The operations of these properties, the Black Horse, Jack Waite, and Bear Top mines make the Murray side of the Coeur d'Alene more active than it has been for many years.

(Special Correspondence).—On Monday, July 3, 1911, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 166, of $65,400. This makes the total amount of dividends paid $12,832,650.

San Francisco, July 4.

MONTANA

SILVERBOW COUNTY.

Work has been started at the Pilot Butte mine, and after the water has all been removed from the shaft, sinking will be commenced. Cross-cutting from the 1200-ft. level of the Black Rock mine of the Butte & Superior to the Pilot ground is progressing favorably. The East Copper Mining Co. has filed its report to the assessor for taxation purposes, showing the operations for the year ended May 31. The net proceeds are reported as $118,986. The ore mined was 89,888 tons; value per ton, $15.31; gross value, $1,376,253; cost per ton for mining, $3.79; total cost of mining, $340,400; cost per ton for treatment, $5.33; total cost of treatment, $478,829; smelter deductions, $184,202; paid for freight, selling, etc., $226,983; cost of improvements, $26,850.

The Butte & Superior Co. shows net proceeds of $3722. There were 131,038 tons of ore mined, the yield per ton being $5.26. The cost of mining per ton was $2.50 and the cost of reduction per ton $1.65. The Butte-Alex Scott during the six months it was in operation showed a loss of $2818. The previous six months extensive development work was carried on, there being paid for labor and supplies $103,097. During the last six months during active mining operations there, 107,358 tons of ore extracted yielded $15.28 per ton.

NEVADA

NYE COUNTY

(Special Correspondence.)—On the 265-ft. level of Midway No. 4, the south vein has been driven on about 200 ft. It averages 12 in. wide, the ore running into milling grade. On the 345-ft. level a promising vein running 4 to 8 ft. wide was recently found. The control of the Manhattan Dexter Mining Co. passed into new hands as the result of the election at the annual meeting, held in this city. R. C. Moore was elected president; W. B. Pittman, vice-president; Eugene Howell, treasurer; Fred Brown, secretary; William Keith and Percival Nash, directors. The contest developed considerable spirit. It was decided that only the secretary should be a salaried officer, and that every endeavor be made to operate the property along most economical lines. Recent devlopments in the mine were reported encouraging. The Blue Jacket mine at Round Mountain is sending out steady shipments of fair-grade ore, mostly from the lease operations. Several consignments of ore ranging $20 to $40 per ton have been treated at the Daisy mill.

Tonopah, June 17.

(Special Correspondence.)—The new vertical shaft at the Big Four has attained a depth of 300 ft., and the showing is said to be good on the new level. The vein is 3 to 10 ft. wide, and assays $50 to $150 per ton in gold. Sixty tons of $50 ore are being extracted daily from the 300-ft. level. The new shaft was sunk on the Poak-Steen-Chapman lease, on blocks 11 and 12. It is estimated that the value of the ore blocked out between the 210 and 300-ft. level will aggregate $100,000. An Ingersoll-Rand 12-drill compressor, 75-hp. electric hoist, pump, and other equipment was recently installed. The pump has a rated capacity of 150,000 gal. per day and is at present handling 140,000 gal. The flow of water on the 300-ft. level continues heavy. Two other leasing companies are active on Big Four estate. Bath brothers' lease on Union No. 2, belonging to the Litigation Hill Merger Mining Co., continues to send out rich ore, a recent shipment to the War Eagle mill yielding $4487. A 25-hp. electric hoist is being installed, and another shift is about to go on. The shaft will be sunk deeper and stoping conducted at the 100-ft. point where 60 ft. of milling ore is exposed. It is announced that the Mineral Hill Co. will immediately commence the driving of an adit to intersect the vein opened by the Mineral Hill and St. Paul leases on the East Side M. & L. Co. on the Mineral Hill estate. San Francisco people are principally interested. Leasing is active throughout the district, and the camp is showing great improvement.

Manhattan, June 30.

WHITE PINE COUNTY

(Special Correspondence.)—The Nevada Consolidated company is shipping some ore from the Liberty workings, but only a sufficient quantity to clear the way for further development. The Nevada Consolidated has obtained an option on the Los Angeles group, adjoining the Cumberland Ely on the east, and has commenced prospecting with churn drills. Ely Centennial has commenced the sinking of a 100 ft. winze on the southwest lateral. The lateral is about 1160 ft. in from the adit portal, and the winze is at a point 475 ft. from the mouth of the lateral. Boston Ely has two drills at work. The jasperoid formation has been found 280 ft. west of the 1245-ft. level. The Ely Consolidated reports the discovery of two new orebodies in the Zack shaft. The first vein shows a thickness of 9 ft. and was encountered 40 ft. below the 500-ft. level. Assays of the ore run 5.4 to 8.7% copper and $1.07 to $307 in gold and silver. The second orebody was found about 30 ft. lower, but its extent and value are not yet known. It is expected to attain the 600-ft. level soon. James Quinn is superintendent.

Ely, June 22.

OREGON

JOSEPHINE COUNTY

The Sterling Gold Quartz M. Co. is operating at Mineral Hill, 9 miles southwest of Medford, where two veins of gold and silver ore have been developed by a series of cross-cuts. The work is in charge of R. L. Ray, and the company is composed of Medford people. Some of the ore is high grade.

The three claims owned by W. H. Ramsey are at the head of Slate creek, 20 miles south of Grants Pass. Adolph Maier recently examined the property and reports, according to the *Rogue River Courier*, that there are two veins, one 20-ft. wide, carrying heavy sulphide and some oxidized ore, and one 8-ft. wide carrying oxidized ore, the first being on the contact of serpentine with slate, while the latter is a fissure vein. The development work consists of a 50-ft. adit and a 20-ft. prospecting shaft. The general average of amalgamation tests was $24.80. The property is 1½ miles from a good wagon-road.

WASHINGTON

FERRY COUNTY

The winze below the 300-ft. level of the Lone Pine mine is down about 115 ft. in a body of ore 12 ft. in width, which is reported to assay from $14 to $40 per ton.

The smelter returns have been received from 47½ tons of ore from the Knob Hill mine, which assayed 6.36 oz. gold and 12.55 oz. silver, bearing a market value of $133 per ton. The total gross value of the shipment was $6058 and the net return $5524. The shoot of ore from which this carload was extracted is 4½ ft. wide. The mine is sending a carload of ore daily to the smelter. There are 14 carloads in transit and at the Trail, B. C., smelter to be heard from, and two more will go out tomorrow.

A clean-up at the Rathfon Reduction Works on tailing from the Old Republic P. & R. Co. mill is reported at $8.50.

KING COUNTY

It is reported that the Standard Oil Co. will establish a million-dollar distributing plant at Richmond Beach on Puget Sound. It is further rumored that the Shell Royal Dutch company is planning to construct a station to compete with the Standard Oil.

UTAH

BEAVER COUNTY

The Majestic Copper M. & S. Co. has been at work lowering the water in its workings. Its pumps have a capacity of 900 gal. per minute and are able to handle the water easily. The shaft has now been sunk from the 500 to the 600 ft. levels, on the latter a drift has been driven 260 ft. east, where, on June 27, 4 ft. of good ore was found. By driving 40 ft. to the west an ore-shoot found 230 ft. above should be cut. During the past year 13 cars of $19 ore have been shipped from the working on the 500 ft. level.

CARBON COUNTY

A carload of machinery has been shipped to Castle Peak to be used, it is said, in opening up the old Baxter claims of the gilsonite workings at that place. G. E. Stewart, field superintendent for the company, who has charge of the property, says that it is expected to mine 300 tons per month.

JUAB COUNTY

The directors of the Iron Blossom will meet on July 10, and there is much speculation as to whether the regular quarterly dividend of 10c. per share will be increased on account of the recent find of ore. Driving is now in progress on the 600-ft. level to cut the new orebody. The shipments from the Tintic district for the week ended June 30 were: Centennial-Eureka, 40 cars; Iron Blossom, 36; Dragon Iron, 27; Bullion Beck, 10; Gold Chain, 10; Colorado, 9; Grand Central, 9; Chief Consolidated, 6; Uncle Sam, 6; Gemini, 6; Scranton, 4; Opohongo, Mammoth, Black Jack, and May Day, 3 each; Sioux Con., Eagle & Blue Bell, and Lower Mammoth, 2 each; Yankee, Eureka Hill, and Swansea, 1 car each. Waldemar Lindgren has been in Tintic recently, but has now returned to Washington, leaving an assistant at work upon the revision of the report upon the Tintic district, issued in 1896.

CANADA

ONTARIO—PORCUPINE

The Gibbons claims have been sold to an English syndicate, and the first payment has been made by Lindsey Morton, who represents the buyers. The vein is said to be 10 to 15 ft. wide and gives high assays. At the North Dome the Dome Extension vein has been uncovered for 270 ft. along the southeast corner of the North Dome. The Portisdale has a good vein on its property, which is the most northerly in Tisdale. The 50 claims purchased from the Timmins-McMartin-Dunlap company by Bewick, Moreing & Co. have been organized as the Ontario Porcupine Goldfields Development Co., with 120,000 shares at £5 each, or a total of $3,000,000 capital; it is expected that £6 per share will be realized. The syndicate has 2000 acres of ground which will be developed under the management of Bewick, Moreing & Co. Gerrard Lovell is manager and Cyril Wanklyn is chairman of the board of directors. Some $60,000 worth of gold from Porcupine has been sent to the Ottawa mint and the first gold coins, bearing the head of George V, have been struck. The prospects at Swastika are showing up well and the outlook for the new camp is highly encouraging.

COBALT, ONTARIO

The figures for the production of the Cobalt mines for the first quarter of the present year have just been made public. During the quarter, 7,530,487 oz. of silver, valued at $3,708,544, was produced. This is less than for the corresponding quarter of 1910, but the output of silver shows an increase of 1,130,560 oz. Included in the total production is the 132,900 oz. from Gowganda and Elk Lake and 66,795 oz. from South Lorrain. The concentrate shipped amounted to 1974 tons, and 3786 tons of ore was shipped. The gold production of Ontario for the quarter was 1813 oz., or $33,990. When Porcupine gets into swing this will be largely increased. Copper and nickel showed decreases of $357,074 and $1,131,024, respectively. The following list gives the production for the quarter:

	Value.
Gold, 1813 oz.	$ 33,990
Silver, 7,530,487 oz.	3,708,544
Copper, 2121 tons	303,240
Nickel, 4124 tons	884,992
Iron ore, 11,545 tons	24,404
Pig iron, 115,454 tons	1,823,717
Cobalt and nickel oxides, 107,846 lb.	29,882

MEXICO

CHIHUAHUA

The Rio Plata Mining Co. declared a dividend of 2c. per share, payable June 30, 1911. This has been a regular quarterly disbursement. The property consists of a mine and mill, situated on the Rio Setentrion, in the Sierra Madre, southwestern Chihuahua, forty to fifty miles from the Kansas City, Mexico & Orient railroad. The mine is developed by means of a series of adit-levels by which the vein is opened to a vertical depth of 600 to 800 ft. The ores comprise quartz, carrying silver as sulphide, bromide, and metal, in iron sulphide. The 25-stamp mill is equipped with tables, Wheeler amalgamating pans, Pachuca tanks, and Moore filters. Machinery is operated by electric power, generated at the company's hydro-electric plant. The ore is conveyed from the mine to the mill over a 1400-ft. aerial tramway. The company is controlled by New York people, H. W. Miller being president. Operations were commenced here in 1907.

RIO PLATA MILL.

(Special Correspondence.)—At the El Rayo mine, ten miles from Santa Barbara, belonging to the Mines Company of America, a new ore-shoot has been opened on the new Comet vein to the north of the ore-shoot which has been under development for several months. This new vein has been tapped by a cross-cut from the upper San José tunnel, and 600 ft. south and 350 ft. lower, by cross-cut from the third level. Both cross-cuts have disclosed ore running from $15 to $20 per ton, and it is expected that the ore-shoot is continuous between the two points of exploration. By advancing the Pettit tunnel 300 ft. this level, 350 ft. lower than the lowest cross-cut, will cut the orebody. The company has been operating continuously. Its net earnings for the first four months of 1911 were $119,599. During that period there was mined and treated 18,100 tons of ore. Its regular quarterly dividend of 2¼% is payable July 25.

Santa Barbara, June 20.

(Special Correspondence.)—Operations at La Republica mine during May were as follows: Tons milled, 1167; production, ₱72,637.54; operating charges, ₱48,281.64; construction charges, ₱4562.33.

Casas Grandes, June 28.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. B. LAMB is at Toronto.

MYLES FLYNN is in London.

R. GILMAN BROWN is in Russia.

W. H. KNOX has gone to Siberia.

F. G. CORNELL was in New York.

GEORGE R. ROGERS is at Porcupine.

GEORGE E. FARISH is in New York.

PHILIP ARGALL has gone to Alaska.

C. B. LAKENAN is in San Francisco.

A. S. DWIGHT is traveling in the West.

HEINRICH RIES was in Canada last week.

A. B. WILLMOTT has returned to Toronto.

OTTO SUSSMAN has returned to New York.

COURTENAY DE KALB is returning to Mexico.

STEWART W. YOUNG is at Carmel, California.

EUGENE COSTE has moved to Calgary, Alberta.

F. J. H. MERRILL has returned to Los Angeles.

D. C. JACKLING has returned to Salt Lake City.

CHARLES E. DUTTON has returned to Goldfield.

GELASIO CAETANI has returned to San Francisco.

WALTER FITCH is at Salt Lake City for a few days.

H. H. SUTHERLAND has opened an office at Toronto.

STANLEY LECKY has returned from western Ontario.

WALDEMAR LINDGREN will be at Salt Lake City July 12.

J. B. TYRRELL has returned from the Swastika district.

LAWRENCE N. WAGNER was in San Francisco last week.

J. P. KEENE will be at Alta, Montana, for the summer.

R. B. NICKERSON has returned to Ontario from New York.

J. A. HOLMES will be in Seattle next week on his way to Alaska.

ROBERT E. CRANSTON is examining placer properties in Idaho.

J. NELSON NEVIUS was in San Francisco and has gone to Oregon.

W. G. PERKINS is visiting the Kyshtim works, in the Urals, Russia.

OWEN LETCHER will return to Johannesburg from London by way of East Africa.

KIRBY THOMAS is making mine examinations in the Cobalt and Sudbury districts, Ontario.

SUMNER S. SMITH was in San Francisco and has gone to Portland on his way to Alaska.

W. G. DROWN is manager of the Columbia mining properties at Angels Camp, California.

B. B. THAYER sailed for Europe July 1; he expects to return to New York in September.

A. J. EVELAND was in San Francisco and will go to Shasta county and to British Columbia.

WILLIAM J. COX has returned to Denver from a visit to the Santa Gertrudis mine, Pachuca, Mexico.

THOMAS H. TULLOCH is mine superintendent for the South Utah Mines & Smelters, at Newhouse, Utah.

R. H. CHAPMAN is doing topographical survey work on Vancouver Island for the Canada Geological Survey.

R. J. CANNON has left San Francisco on his way back to Philadelphia. He expects to go to Colombia next month.

ROY HOUSE, GEORGE SPIETZEN, and NIEL HARRINGTON, formerly with the First National Copper Co., have left for South America.

G. H. BLAKEMORE is investigating the various methods of handling ore in the United States, and is at present at the Utah Copper Co. mine.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

Contract of Sale of Minerals—Damages for Breach

A contract for the sale of mineral rights in certain lands for which the seller held options, gave the purchaser the option to furnish funds to have the lands drilled, but under the option only such could be taken as were shown to contain a coal vein or under the option all the lands must be accepted without drilling. In an action for the breach of this contract by the purchaser refusing to take the lands or to furnish a certain drilling fund provided, the seller was not entitled to recover the contract price for all the lands and also the cost of drilling machinery purchased by him.

Eisleben *v.* Brooks, 179 Federal, 86.

Mechanic's Lien on Mining Claim

The statute of New Mexico requires a person claiming a lien on mining property for labor to file a statement of his demand with the statement of the terms and conditions of his contract. Under this statute a claim for a lien reciting that the claimant agreed with the owner or operator of the mine for a specified sum per day and board is sufficient. So a statement of the general nature of the materials furnished, or labor performed, with the amount claimed to be due therefor after deducting credits is sufficient. Accordingly, a statement of the claim for a lien reciting that the claimant performed labor in the construction of a mining claim on land is sufficiently definite and includes different kinds of labor, for all of which a claimant may have a lien.

Gray *v.* New Mexico Pumice Stone Co., (New Mexico) 110 Pacific, 603.

Location of Mining Claim—Declaratory Statement

An amended declaratory statement of the location of a mining claim which stated that a discovery was made of a vein of mineral-bearing rock in place, and that a shaft 4 by 8 feet and more than 10 feet deep was sunk at the point of discovery, is sufficient to show that the shaft was sunk on the vein for a depth of more than 10 feet and that it must have cut the vein at that depth. The original and declaratory statement of a mining claim made, respectively, on February 25, 1904, and May 23, 1905, cannot be affected by discovery of a conflicting claim made December 8, 1904, and where an amended declaratory statement was filed January 8, 1909, as the amended declaratory statement in each case related back to the date of the original declaratory statement.

Giberson *v.* Tuolumne Copper Mining Co., (Montana) 109 Pacific, 974.

Persons Entitled to Mechanic's Lien on Mining Property

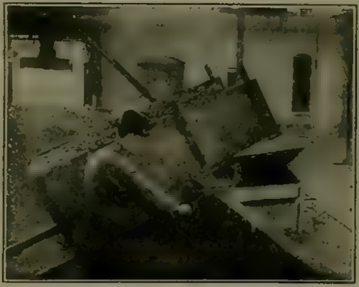
The statute of New Mexico giving a lien for labor in a mining claim, gives a lien for manual labor performed on a limestone mining claim, and this includes labor in the care of horses used in the mining operations, for labor in a lime-kiln, closing lime-bins, and gathering up tools at the lime quarry and kiln. The statute includes every person who deals directly with the owner, and who, in pursuance of a contract with him, performs labor or furnishes material, and every such person is an "original contractor" within the meaning of the statute giving every original contractor a lien. And the term "mining claim" within the meaning of this statute means in the mining country a portion of the public mineral lands of the United States to which a qualified person may first obtain the right of occupancy and possession by means of location, or to which title may be obtained by pursuing prescribed methods therefor.

Gray *v.* New Mexico Pumice Stone Co., (New Mexico) 110 Pacific, 603.

Commercial Paragraphs

On June 1, 1911, the **Sprague Electric Co.** was merged with the **General Electric Co.** of Schenectady, N. Y. Its business will be conducted under the name Sprague Electric Works of General Electric Co. The manufacture and sale of the lines of apparatus and supplies heretofore exploited by the Sprague Electric Co. will be continued by the Sprague Electric Works of General Electric Co. under the same organization, with D. C. Durland in responsible charge as general manager, and with the assurance that the characteristic high quality of product and efficiency of service to its customers will be maintained. All correspondence should be sent to the Sprague Electric Works at the same address as in the past. The offices of the Sprague Electric Works will be continued as heretofore, with main offices at 527-531 West 34th street, New York City, and branch offices in the principal cities.

The **Stephens-Adamson Mfg. Co.**, of Aurora, Ill., has recently produced an unloading car chute that is claimed to be a great saver of time and labor in unloading gondola cars. It consists of a chute or small car which has a capacity of 1½ cubic yards. This chute rests on a framework inside the car while it is being loaded. To empty it into the wagon, it is easily raised by a winch on the frame and then tipped into such a position that its contents slide into the wagon with no spill on the ground.



RAISING THE CHUTE.

The frame is entirely separate from the chute, acting merely as a supporting device to hold it first while it is being loaded, and later acting as a dumping device. This framework rests on the car across both sides, as is shown in the above cut, or, when sufficient material has been taken from the car, the frame is tipped and the rear end is allowed to rest on the bottom of the car. This permits the chute to be brought down inside, and does away with all shoveling over the edge of the car to the wagon. In either of these two positions of the frame the dumping action is the same, and the amount that the chute is tipped is always easily controlled by the operator at the winch.

DUMPING POSITION ON FULL CAR.

The construction is strong and the unloader can easily be placed in working position or moved to another car by two men. It can also be taken apart very quickly for shipment or for easier moving. It is entirely self-contained and is adapted for use on any open car.

EDITORIAL

MR. DANIEL GUGGENHEIM must have let his imagination run away with him, according to the comment he has evoked

POLITICAL INTEREST has centred in northern Africa lately, and a recent interesting development is the proposal by a Spanish syndicate to build an 1800-mile railroad across the continent.

GOVERNMENT FINANCES show an encouraging condition of affairs. The receipts for the last fiscal year were ten million more than the estimated expenditures, which were six million less than the estimate. The Federal corporation tax has yielded over twenty-eight million dollars in revenue.

THE AMERICAN CHEMICAL SOCIETY met in Indianapolis at the beginning of this month. The seriousness of technical discussion was relieved by social functions, and practical demonstrations to the food chemists were afforded by the complimentary luncheons given by various manufacturing companies.

SYMPATHY of engineers the world around goes out to Mr. Gardner F. Williams and his family, over the loss of Mrs. Williams when the steamer *Spokane* was wrecked in Seymour narrows off the coast of British Columbia. Mr. Williams, Mr. W. W. Mein, and their families, were on their way to Treadwell and other points in Alaska at the time of the accident.

NEXT TUESDAY the Postal Commission will begin its work of investigating the cost of handling and transportation of second-class mail, and fixing the rate. It is also announced that the express companies will, on August 1, reduce rates; as much as 50 per cent in some cases. The Interstate Commerce Commission is now engaged in an investigation of the rates charged by express companies.

THE JUNE ISSUE of our London contemporary, *The Mining Magazine,* is full of interest. Mr. M. H. Burnham continues his analysis of 'The Finance of a Mine,' to which Mr. Harold E. Fern adds some interesting discussion. The veteran Cornish engineer, Mr. J. H. Collins, who is known in America both for his own attainment and that of his sons, describes the china clay industry of Cornwall. The editorial comment is at once incisive and graceful, the tribute to the late W. S. Gilbert being a notable example.

CARE OF EMPLOYEES is not the least of the responsibilities of the manager of a large enterprise. On another page we give the text of the Workmen's Compensation Act recently passed in the State of Washington. The ends such acts are designed to meet are already served, in the case of some corporations, by company regulations. At the Copper Queen for instance, the Employees Benefit Association paid $3650 in death benefits, $9565 for injuries, and $6556 for sickness, during the first five months of this year; the cost of administering the fund being 3¾ per cent.

A WELL KNOWN ENGINEER has advanced the theory that the heat generated in large cities has affected their climate. This is not a remarkable statement; it is more remarkable that the effects of large aggregations of humanity upon climate are not more noticeable. The large quantities of heat and CO_2 poured into the atmosphere of a large city might reasonably be expected to have much ill-effect, but, except for objectionable dust, the air of a city is not markedly inferior to that of country districts.

TWO PROMINENT FEATURES of interest in the mining world just now are, how may the coal resources of Alaska be developed, and how can smelters continue to exist in settled districts. The rejection of the Cunningham claims followed naturally from the law and the evidence, and public sentiment approves. But the prevention of illegal development of Alaskan mineral resources is not enough. What is urgently needed is far-sighted constructive legislation which will permit the development of industry on the Pacific coast of America. Fuel-oil has its place, which it fills excellently, but it can not meet all the needs of fuel consumers, and a cheap and copious supply of good coal will aid the development of every other industry without retarding that of oil production. The development of small claims into producing coal mines is not feasible. Legislation which will allow the development of the coal resources of Alaska is a need of the body politic, not of the Pacific coast alone, for that which benefits one part of the body benefits all. Smelting companies have, of recent years, found their difficulties external rather than internal. One smelter after another, west of the Rocky Mountains, has been obliged either to discontinue work or to move its plant, by order of court, until it has become a problem whether a smelting industry can hope to survive in many districts. It is almost impossible to accept the claims as to the damage sustained at their face value. The largest copper refinery in the world is within the city limits of New York, which include a large copper smelter as well. Copper and lead smelters operate in peace among the fertile farms of New Jersey. It is difficult to understand how the differences of climate and situation can give rise to such different effects in the West. Possibly the Bureau of Mines will speak with authority, when opportunity has been afforded for the necessary researches.

Steel Production in the Far East

On another page Mr. T. Haga, in his interesting description of the newly established Nippon Steel Works, draws attention to the connection between the iron industry and military strategy in the Far East. When China and Japan began to develop in consonance with modern progress, statesmen soon recognized the necessity for internal supplies of coal, and iron and steel, so that the nation might not be utterly dependent upon imports while engaged in war. The Japanese government established a blast-furnace and steel plant, at Wakamatsu, in the northwestern part of the island of Kyushu, which has not been very successful in operation. The strategic value of steel plants in Japan is much lessened by the fact that the domestic supply of iron ore is inadequate to form the basis of an extensive industry. Possibly the Korean ores, just beginning to be developed, may furnish the necessary supply. Dalny (Tairen) seems an excellent site for a blast-furnace plant, but since China can repurchase the town and improvements at cost price in 1939, there is comparatively little incentive to begin to develop an industry there.

The Chinese iron works have been more successful, due to an ample supply of good ore and coke, as well as efficient foreign supervision. Founded by the statesman Chang Chih-tung, and developed by Sheng Hsuan-huai, they now turn out many tons of excellent steel rails each year, and have exported pig iron to both Atlantic and Pacific ports. The low cost and efficiency of native labor forms, next to the supply of good ore and coke, the mainstay of the Chinese iron industry. A contemporary journal, in citing the high cost of the Canton-Kowloon railroad as an example of the inefficiency of cheap labor, illustrates rather the futility of attempting comment on what is not understood. The high cost of the Canton-Kowloon railroad was due to the fact that in a distance of nine miles, seven bridges of a total length of span of 3250 feet were required; nor are the Chinese the only people who have been unable to build railroads cheaply under foreign supervision, when there were contracts to be let to foreign bidders. The index of efficiency—output divided by cost—of Chinese labor is at least as high as that of British or German, and it is not at all unlikely that before the present century has passed China will have taken a place as one of the more important steel-producing countries.

Inadequacy of Language

Inadequacy of language in the expression of an idea may arise either from a lack of knowledge of words and of skill in their use, or from the inherent inadequacy of our English language; just as unsatisfactory achievement in chopping wood may be due either to the inefficiency of the wood-chopper, or to the dullness of his axe. So much has been said of the lack of skill displayed by engineers in the use of language, both spoken and written, and their lack of knowledge of good English, that we intend to speak rather of the deficiencies of the English language, as displayed in its use in technical literature. To further narrow the discussion we will speak only of the language used in the technical literature of mining. The English language has developed from its hybrid forbears with little regard to the needs of mining men who, like the conies, are but a feeble folk, unable to fix lines of progress, but perforce content to adapt, so well as they might, that which was already available to their needs. Being at first but illiterate men, they laid foundations upon which the superstructure reared through the years stands somewhat askew. None can foresee what the needs of a language will eventually be, and a plan that was most encouraging may, in the end, prove totally inadequate. Chinese is the best example of this, where the beautifully simple method of having each idea expressed by a certain sound in speech and by an ideograph in writing, early exhibited its limitations and now falls prostrate before the demands made upon it by the introduction of chemistry, physics, and their application to industrial life. The English language exhibits a similar inadequacy, though not so marked.

The mining engineer who wishes to write both accurately and pleasingly is at once upon the horns of a dilemma. Rhetoric forbids the wearisome reiteration of a word. Science demands that in accurate writing the term used shall first be defined and afterward used in the proper sense. What shall he do? There are no synonyms for many important words; and the use of so-called synonyms is but a scientific makeshift, for there are no true synonyms. If a true synonym existed, the less convenient of the two words would drop out of use, as the gold one-dollar piece has done. Usually he employs words and phrases which he conceives to be synonymous, with but indifferent success from a rhetoric standpoint and with great bewilderment to the reader. 'Broad' has not the exact meaning of 'wide', neither does 'variable' mean the same as 'varying,' nor is 'noted' exactly equivalent to 'seen' or 'heard.' Passing to more technical words, a machine may be 'installed,' a mill can only be 'constructed' or 'erected,' while a new method of working may be 'inaugurated.' The first and last of these words are so often misused that some would have us discontinue using them, perhaps on the doctrine that "If meat make my brother to offend, then will I eat no meat." But our choice of words is already so restricted that we can ill afford to relinquish any.

But worse than the fact that there are no two words in English which express exactly the same idea, is the absence of any good manner of stating some ideas. Such an expression as 'Smith has opened up the vein on the fourth level where it carries values running from eight to ten dollars per ton' introduces three such difficulties. 'Opened up' is awkward and inaccurate; he did not open it like a chest, but 'found' will not do; he knew the vein was there, having found its outcrop, perhaps years before. 'Picked up' and 'broken into' are equally as bad; they are awkward, and the former has the sense of lifting and the latter of entrance into a space, neither of which here applies. 'Intersect' should be restricted to lines, 'struck' and 'encountered' have a sense of antagonism and are totally wrong, and 'cut,' while it will do, is much overworked. 'Values' is even more puzzling. What does it mean? Presumably the minerals that are a source of profit when the ore is treated. Conceivably the 'values' have no value, for it may cost more than $10 per ton to extract them. The word is bad therefore. By reconstructing the sentence we may say that the ore 'carries gold and silver worth $8 to $10 per ton,' which is as useful as turning a glove inside out; as before, they may be worth nothing. No one can know what the actual worth or value of a ton of ore is except from the books of a company engaged in treating it. It is further conceivable that a ton of ore actually worth $5 to A may be worth $8 to B, either because the latter can extract more of its content at a lower cost, or because, if the ore be silicious, A is engaged in smelting an ore mixture that is too silicious, while B is smelting basic ores. 'Worth' and 'value' should not be used in describing ore which has not been extracted, except with the qualification 'estimated value.' Ore containing one ounce of gold per ton is not ore worth $20.67 per ton; to say it 'contains gold worth $20.67 per ton' is better, but has a tendency to shift the attention from the real point, the true value of the ore, which may be zero. When this theoretic 'value' is derived from several metals such as lead, gold, and silver, the attempt to be accurate leads to the use of awkwardly long expressions, which, if often repeated, are irritating and clumsy, and in any case are less forceful; for in using ten words to express what can be put in two the effect is like that of using a feather bolster to drive a nail. The idea 'running from eight to ten dollars per ton' casts defiance in our teeth. The ore is not engaged in a foot-race, but to say that it 'averages' eight to ten dollars per ton would be incorrect. The average, if we could determine it, might be $8.97; it could not have more than one value. Neither does the 'value' of the ore 'vary from eight to ten dollars per ton'; it might do so if the market price of the metals fluctuated, but this is not what the writer was endeavoring to say. The ideas in the sentence given are clear enough, but our language is inadequate to express them concisely and accurately.

Many other phrases might be given, but space permits of but one more. 'The directors are contemplating the erection of a mill' is the briefest and most accurate way of expressing its contained idea, yet it brings up a distracting mental image of those eminent dignitaries perched upon stumps and nail-kegs, gazing earnestly, that is neither serious nor profitable. The use of foreign words and phrases may sometimes be indulged in, either because the foreign phrase has a shade of meaning that cannot easily be expressed by any combination of English words, or because the reader or hearer will only know one meaning for the foreign word; thus giving it a preciseness which it does not possess for a native, much as Latin words are used in legal phraseology. *Chic* and *petite* have shades of meaning that defy translation, the German past participle *gefressen* requires several words to translate, and the Chinese phrase *pu yao* has much more force than the English 'I do not want it.' The disadvantage of the use of foreign words is that it is not always possible to rely upon the comprehension of the reader or hearer, when their use degenerates into mere affectation, calculated to create an impression. A radical, but unwise, method of overcoming the difficulty is that of the eminent and enthusiastic geologists who recently devised an entire new terminology, the learning of which is a task far too burdensome for most engineers. But with both care and attention much may be accomplished. The careful writer and speaker is conscious of the imperfection of his performance, hewing as close as he may to the line with that blunt axe, the English language.

The Coronation

By T. A. Rickard

Even a periodical avowedly technical must not fail to make reference to an event so commanding as the crowning of the King and Queen of England. To every country of the globe the echoes of the historic celebration have penetrated, even to the mountains and deserts in which the miner seeks for mineral. If those who live in London are weary to satiety with the subject we still owe something to our friends on the velt and on the tundra, to those who may care to receive an impression from one who like themselves has spent most of his life on the frontiers of civilization. To them and to us the ceremonial of June 22 is a pageant rich in suggestion; it breathes of old things dimly understood and of old ways long discarded. In mining we are painfully modern; hence a reversion to the feudal, mystic, and ecclesiastic spirit of the Middle Ages has the touch of the unexpected and the note of the surprising. To an industrial people the militarist idea is as uncongenial as the medieval, and to an empire broad-based on representative government the ceremony between the King and the landed aristocracy seems to ignore irrefutable facts. Moreover scientific men are concerned with realities, although not lacking in imagination; therefore to those engaged in mining the mosaic of survivals at Westminster fails to symbolize the later history of the Empire. In real life the black coats do the work of governing and the gold buttons are the emblems of service. Parliament, under the Crown, rules England; a civilian is the chief of the Government; men without rank hold high place in the estimation of the community. In the Abbey these were only spectators to a quasi-religious drama enacted by individuals whose right to do so was recorded in the College of Heralds. It seems an inexplicable perversion of political progress, and yet it was accepted good-naturedly because the Coronation was regarded as the symbol of imperial unity; to us the King is the one link that unites diverse communities under the British flag; he receives the willing homage of a free people. In their royal progress through the metropolis King George and his consort were acclaimed by men and women who not only took part in a resplendent show but participated in a serious ceremonial. By its omissions not less than by its performance the Coronation suggested the spirit underlying many a British institution, the form of which survives as an anachronism while the spirit changes in subtle harmony with the growth of the human spirit.

Ball-Mill Practice at Kalgoorlie

By M. W. von Bernewitz

So much has been written about the modern stamp-mill that other efficient pulverizers are apt to be overlooked; therefore I make no apologies in presenting this discussion of the modern ball-mill, in this case the Krupp, in the hope that it may be of use to others who have plants in operation, or contemplate their erection. It is doubtful whether the dry-crushing ball-mill is operated with greater efficiency and less cost in any other mining centre in the world than in Kalgoorlie. We have had great experience with them, and with a constant interchange of ideas, each plant is well abreast of its neighbors, until there is practically no difference of opinion as to operation.

The ores in the 'Golden Mile' do not vary much in composition, and, taken on the average, they may be said to be hard to crush. The ore in most of the mines averages 60% silica, the Great Boulder showing as high as 75%. Summary descriptions of the ore milled in the dry-crushing plants follow: the Associated has little schist, rather above average in silica; hard and highly mineralized. The Associated Northern main lode is of schistose character; west lode hard and silicious. The Chaffers ore varies from schistose to hard flinty quartz, with 3 to 5% pyrite. The Great Boulder has very hard cherty quartz with a little schist. The Kalgurli ore is quartz-diabase, varying in hardness according to depth, from schistose to highly silicious; average tough. At the Perseverance the ore is schistose in structure, and contains pyrite and magnetite throughout. South Kalgurli ore averages 60% silica, with little schist, and is considered hard.

The following analyses are from the Associated Northern and Perseverance mines:

	Per cent.	Per cent.
Insoluble	60.60	63.46
Aluminum oxide	5.75	2.06
Iron bisulphide	5.32	6.80
Carbonate of lime	11.19	13.42
Carbonate of magnesia	5.29	6.93
Carbonate of iron	10.23	6.80
Alkalies, undetermined	1.62	0.53
	100.00	100.00

The average ore from the mines is dry enough for milling, although the driest holds from 0.5 to 1% of moisture. Anything above this amount retards crushing. In a stamp-battery, or other type of crushing machine, a great deal of the efficiency depends on having massive foundations. So it is with the ball-mill. A mill on a solid block of concrete will crush better than one on a timber or steel girder, no matter how well braced. A springy support is bad for the gear, and does not allow the mill to be stiff, as it were. This has been noticed especially in the Associated plant built eleven years ago, in which 10 mills were resting on timber girders, and two on concrete piers, the latter doing far better work than any other pair in the plant. The former foundation consisted of a masonry bed, on which stood 12 by 6-in. steel girders with brackets riveted on to support two longitudinal pieces of jarrah 12 by 14 in., across which were bolted three pieces of 12 by 14 for each mill. This would appear to be stiff enough, but the vibration was still bad. Now the big mills are on concrete foundations, reinforced with old wire rope and rails. The Associated Northern, Chaffers, Great Boulder, and Perseverance ball-mills are set on massive concrete foundations; the last mentioned is especially good. Those at the Kalgurli are set on steel girders 8 by 6 in., well braced and apparently firm; while in the South Kalgurli plant they are bolted to a frame of 12 by 12-in. timbers, well braced and standing on a concrete foundation. This seems a small structure, but is free from vibration.

As soon as the foundations for a ball-mill are sufficiently set, and the four bearings for the mill-shaft and pulley-shaft are lined up, the building of the mill can be done rapidly; and with eight men who understand the work a mill may be erected in 24 hours. Everything is simple; the main walls are bolted or riveted to the cast-iron naves, and when in their proper places, are keyed to the mill-shaft. The side-liners are bolted loosely until all the mantle-plates with the grinding plates are in position, then everything may be tightened, all bolts having check-nuts, excepting those on the mantles holding on the grinding-plates, which are riveted. The fitting of the scoops, baffles, and inside and outside screens is quite a simple matter. The feed-hopper is in two pieces for bolting around the shaft, and is lined for the wear of ore dropping in from the feeder. Unless motor-driven, each mill has a fast-and-loose pulley on the pinion-shaft. There are two sizes of mills at work in Kalgoorlie, with the following dimensions:

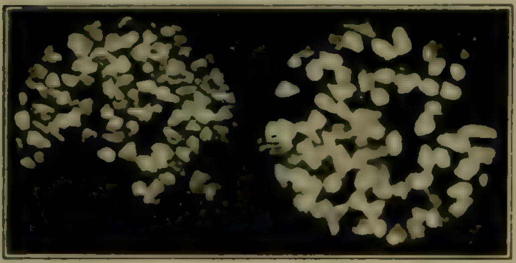
	No. 5. Inches.	No. 8. Inches.
Diameter	89	106
Width	46	54
Mantles for plates	10	12
Inside screens	5	6
Outside screens	10	12
Area of outside screens each	46x26	54x24

The latter item is the full area, not deducting that part of the screen covered by the wooden frame. Approximately, the net screening surface on each mill is 70 and 100 sq. ft. respectively.

The mantles carry four or five grinding, and one perforated plate, which are tightly bolted together. The bolts have a feather on the tapered portion which fits into the plates, thus preventing turning during tightening. Bolted to the bottom end of the mantles are the baffle and scoop plates, which return the oversize to the mill. The whole mill is enclosed in a tight-fitting casing, which is made in convenient sections for removal during repairs. The spur-wheel is keyed to the mill shaft, is usually of cast iron, and should last, if well greased, fully four years, while the pinion lasts about half that time. The loose pulley runs on a sleeve, which must be well greased to prevent seizing. At one of the new mills at the Associated, a new idea for loose pulleys has been devised, a cast-iron bracket with an extended hollow sleeve, bolted to the plumber block farthest from the mill. The pinion shaft revolves in this sleeve, and the loose pulley rests on it. When the mill is working, the pulley is at rest, thus preventing much wear at this point.

It is found that a good, stiff, light grease is best for all bearings on a ball-mill. A few turns of a grease cup twice in eight hours is generally sufficient. For the gear, old, though clean, grease from other bearings is good enough. Properly fitted gearings, when well greased, make little noise. When driven from a main driving shaft, a tight and a loose pulley are required; but when motor-driven, the former only is necessary. The Great Boulder people are fitting clutch pulleys on the main shaft with satisfactory results. An 8-in., 6-ply balata or rubber belt is strong enough for a No. 5 mill, and a 10-in., 8-ply for a No. 8. From 24 to 26 r.p.m. is the correct speed for the No. 5, and from 21 to 24 r.p.m. for the No. 8. It is generally admitted that the latter speed for the larger mill is quite safe and shows much greater efficiency, although the makers stipulate the lower speed. Mills are loaded with one to two tons of 5-in. steel balls, according to size and hardness of the ore to be crushed; there is no advantage in using several sizes of balls. Indicator diagrams at the Associated Northern and Associated have shown that the No. 5 mill takes from 18 to 23 hp. when in an average working condition, and the No. 8 consumes 60 hp. Where motor-driven, as at the Perseverance and South Kalgurli, the ammeters register 60 to 65 amp. at 550 volts.

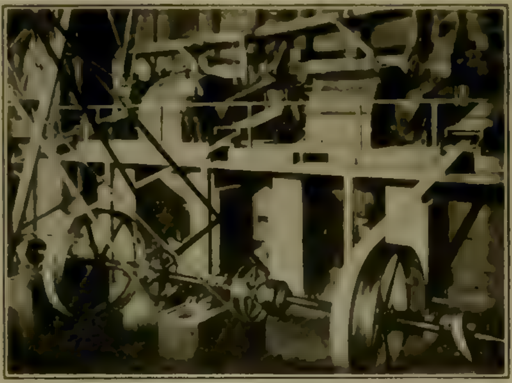
It is found advisable to have the storage-bin for coarse ore a few feet behind the ball-mills, as it allows the construction of a proper chute with a gate, and a long feeder, thus giving a steady flow of ore. When the bin is right over the mills, as at the Associated as originally erected, this can not be relied on, ore often rushing out and filling up the mills. For the protection of employees, keeping the plant free of dust, and the better working of a ball mill, a strong fan attached to the mill by large piping, is very necessary; and a plant properly arranged in this detail is a pleasure to work in. A couple of Sturtevant or similar type fans about 4 ft diam. running at 800 to 1000 r.p.m. should keep eight No. 8 mills clean, and a 3-ft fan like that at the Associated Northern, running at 800 r.p.m. is very effective for four No. 5 mills. A 4-ft motor-driven fan at the Associated takes 5 amp. The suction and delivery pipes should be fitted with sliding doors to facilitate cleaning. The draft in the suction pipe at the Associated Northern averages 0.34 in. The fan generally blows the dust into a canvas-lined house, in which it readily collects, or as at the last named mill, it is blown into the second hearth of the Merton furnaces. At the Perseverance, the dust is collected in cyclone arresters, thence into the main furnace flue. A strong draft aids in keeping the screens clean, especially when the ore is at all damp, as the steamy air is drawn away. When dry crushing with stamps at Waihi in New Zealand, in 1894 to 1899, the beneficial effect of a fan was very noticeable. The amount of dust lost in dry crushing is difficult to estimate, but from observations I should say it would total 1 per cent.



30-MESH PRODUCT × 15 DIAM. 100-MESH PRODUCT × 32 DIAM.

The ball mill feeders are usually of the grasshopper or shaking tray type, that is, a sloping tray with sides 6 in. high at an angle of about 25°, suspended at the discharge end by a chain or rod from a beam above, and the top end supported by two iron legs, fitted loosely to the under side of the tray, and to a timber support near the floor. At the back of the feeder tray is a tappet, and on a shaft is a single, double, or three-armed cam, adjustable to give up to 1 in. lift to the feeder. This pushes the feeder back, which, when released, drops forward by its own weight, discharging an even feed into the mill. It is the custom now for each mill to have its own feed-shaft driven by a 3-in. belt from a pulley fitted to an extension of the mill axle. The mills at the Perseverance are so fitted, the whole being very neat and effective. South Kalgurli mill feeders are arranged with a perforated tray, through which the fine ore passes on to a shaking tray fitted with a 27 by 27-in. screen, this in turn screening all that portion already fine enough, it passing to the conveyor beneath. One was tried for some time at the Associated Northern, but it did not increase the capacity of the mill to any extent. The arrangement requires close watching. Feed naves are arranged for left and right-hand feeding; by this means mills may be run in pairs, the feed hoppers being reasonably close together, and it may be remarked here that mills should not be too close together, as plenty of space is required for repairs, etc. The balls are fed in either through the manhole door or feed-hopper, and ore fed in until the balls are well mixed with it. A mill should not be started without feed, as the balls knock the plates about badly. Unless a mill is motor-driven, it would be difficult to arrange for an automatic feeder. I have not heard of any, but think that one could be fitted up, depending on the increase of power consumed over a set point. If a mill takes 60 amp. with a full load, and is overfed to 62 amp. then some automatic gear could shut off the feed. Like many other machines, the operation of a ball mill is governed by the sound. This is an important point to impress on mill men, as a poor attendant may easily reduce the efficiency of a mill 25% by inattention. With practice the operator of a ball mill gets expert and can detect a light feed from some distance; a mill running empty simply roars; when light there is a clear metallic sound of balls striking one another; when just right, there is simply a rumbling noise, while in a mill that is full, the balls and ore are carried high enough to fall directly on the mill axle or shaft. This is very bad work, as the shaft is liable to be damaged and worn, and crushing is reduced to a minimum. The remedy for too much feed is, of course, shutting it off until the correct sound is heard. A mill man not too sure about his feeding can easily see this by stopping the mill, and looking into it through the feed nave with a light. The mass of balls and ore should be evenly distributed, and no bare balls should be visible.

The operation of the Krupp ball-mill may be described as follows: The mill is a gear-driven, steel-lined drum, charged with one to two tons of steel balls, revolving at 24 to 26 r.p.m., according to size. The ore crushed by the balls, passes through perforated grinding plates, and is screened by the inside or coarse screen, the oversize being automatically returned to the interior of the mill; while what passes the inside screen is screened by the outside or fine-wire screen, the oversize being also returned to the mill for further grinding. The action of crushing and returning the oversize is ingenious, to say the least, and it will be seen that as soon as the ore is crushed fine enough, it must pass out of the mill. Here lies the efficiency of the ball-mill. In a 5-stamp battery, there is a great deal of unnecessary pulverizing given the ore due to its not being discharged as soon as it is fine enough. In the ball-mill there is little of this, and any machine that discharges its product when it reaches the required size will show high efficiency. As regards the action of the balls, it has been stated that crushing is done by impact; but from careful observations I am perfectly satisfied that this is not so. The only impact which might occur is when the balls drop from one grinding plate to another, a distance of 5 in. in a newly lined mill; and then only some very fine particles would be crushed by impact at this point. The action of the balls is one of pure rolling, grinding, and abrasion. They are lifted up about level with the mill shaft or axle, and then roll back, tumbling over one another, rubbing and grinding the ore fed in. Of course there is a great deal of attrition between the pieces of ore apart from the work of the balls.



NO. 5 MILLS AT THE ASSOCIATED NORTHERN.

This is not mere supposition, but fact, as I have myself seen the action. At the Associated mill, four No. 5 mills are crushing oxidized ore which carries 5% moisture, so coarse screens are used; in fact, the wire screens were removed and the inside ones only used; these being punched steel with 30 holes per square inch. In crushing this ore no dust is made, so by the aid of a portable electric lamp, placed well down in the feed hopper, the balls and ore could be seen plainly. The action observed was simply that the balls and ore were carried up nearly level with the shaft, and on reaching this point began to roll back. There was 1200 lb. weight of light-weight balls used on soft ore, rolling and tumbling about and grinding and rubbing the ore between them. It was a most interesting sight, fully proving that there is no impact grinding. To further prove this, one has only to observe the ore in a mill when it is stopped for repairs. Down to the very small particles, say 6 mesh, it is smooth and round, just as if water-worn in a river where the stones are rounded from a rolling action. Pieces of steel, which come in from the mine at times, are rounded in the mill, although they hinder good work to some extent. If impact were the action in a ball-mill, dynamite, which also finds its way in with the ore, would explode, as it does in a Griffin mill; but it does not, and I assume that it is simply rubbed away. F. B. Allen, director of technical education in this State, with G. Larcombe, instructor in geology, have kindly examined, under the microscope, some ball-mill product which was wet-screened to clean the particles from dust, to see whether they had a sharp fracture or not, with the result that they show the +30 screen product to be somewhat rounded, and the +120 to be with sharp, ragged edges. This shows that the final particles are split by the rolling of the heavy balls, not necessarily by the drop of a ball, as in a tube-mill, as described by H. Fischer in several of the leading technical journals in 1904.

This is also shown by the way the balls keep round in wearing from full size to the smallest, and also the smooth, round pieces of ore and steel. The figure shows micro-photographs of the final particles from a ball-mill, taken by G. Larcombe, of the Kalgoorlie School of Mines.

In table II below will be found the consumption of steel and the life of liners in a mill. Steel consumption is gauged by the weight of balls consumed per ton crushed, and not only by the total balls and liners used, as in a battery where shoes and dies are calculated. The average steel consumption in the ball-mill plants here is 0.55 lb. per ton, while the lunch or grinding plates last about 190 days, perforated plates the same time, and side liners about double this life. Manganese steel of the Hadfield or Krupp make is very satisfactory. As regards the capacity of ball-mills or other machines, the efficiency depends upon the quantity crushed per horse-power consumed. A No. 5 Krupp mill crushes 43 tons daily of ordinary sulphide ore, and the No. 8 100 tons; dividing this by the horse-power consumed, 18 to 23, and 60 to 65, 2.1 and 1.6 tons per horse-power respectively is obtained. In a small plant of 100 tons daily capacity, the No. 5 is a useful unit, but in a large plant the No. 8 is the best size. They have large capacity, run smoothly, and occupy little more space than the smaller unit. The quantity of ore crushed as given above is from actual weighing in some cases, and from the tonnage crushed divided by the hours run in others. On quartz the capacity of a No. 5 mill is lower, being about 36 tons per diem. Excellent opportunity of finding out the capacity was had at the Associated Northern, as all the custom ore is weighed.

It is impossible to prevent damp ore of from 1 to 3% moisture, coming into the plant. Then the ball-mill efficiency falls off greatly and the wear and tear is heavier; the feed must be light to prevent the screens clogging, as a steaming is set up, making everything sticky. When crushing dry ore, the inside of the mill gets very hot from friction, a recent test showing up to 135°F. when the outside temperature was 97°. The Kalgurli used to dry the damp ore before milling, but rotary dryers are a nuisance. The soft oxidized ore from the mines is easily crushed in ball-mills, as at the Associated and Associated Northern, by using only 1200 lb. of balls, taking off the outside screens and passing it through the inside or coarse screens. Pans reduce this product quite easily. Actual tests show that a No. 5 mill will crush 82 tons per day, but for 5% moisture the capacity would be greater. The Chaffers has one mill on this class of ore, wet-crushing 93 to 100 tons through 26 by 26-in. screens per diem, using 2400 lb. of balls.

It is advisable to open mills for inspection once a week, unless something goes wrong in the meantime, and every two months the balls should be taken out, weighed, and all balls under 1½ in. diam. discarded, as they are of little use in crushing, and the original weight made with new balls of 18 lb. each. Foreign matter, such as drill ends, bolts, nuts, spanners, etc., accumulate in mills, and as they hinder the smooth work of the balls they must be thrown out. One man at 11s. 8d. per shift of 8 hours can look after eight No. 8 mills; but in smaller plants the mill-man attends to conveyors, elevators, dust pipes, etc. Ball-mills should be fed with no larger ore than that which will pass a 3-in. ring. With fine ore the balls are apt to bed, as it were. Actual weighing has shown that a 3-in. feed is crushed faster and the wear of steel is less than when the feed is 1 in. with a quantity of fine.

Following are grading analyses from ball-mills in our different plants:

NAME	+30	+40	+60	+80	+100	+120	+150	−150
Associated		16.16	15 66	10.46	6.43	3.76	3.46	44.00
Associated Northern		11.20	20.10	8.30	11.80	2.20	2.00	43.60
Chaffers		10.25	13.19	8.60	7.25	2.70	1.71	56.30
Great Boulder	1.00	5.80	14.20	8.70	9.00	2.30	7.00	52.00
Kalgurli		8.20	18.00	13 40	9 10	2.40	2.20	45.30
Perseverance	0 20	3.80	20.60	7.80	5.40	4.00	3.80	54.20
South Kalgurli		10.20	21.20	6.00	2.60	3.10	1.00	55.90

TABLE I

With the exception of the Associated and Great Boulder, where the screens are 30 by 30, 27 by 27 is the size used. They are fairly uniform, although the −150 is low at the Associated, Associated Northern, and Kalgurli for some reason not understood. The ball-mill does not make so much −150 as the Griffin and other pulverizers. The coarse screens used to be fixed to the mill by studs, but a local improvement was introduced in fitting them on with 1½-in. angle iron, bent into a circle, and bolted. A large number of bolts are used in a mill, and their cost is high. For some reason, perhaps because of the expansion of the plates by heat, or loose plates, the bolts break and fall into the mill. Coarse ore then passes through the bolt-hole into the space between the mantle and screens, causing the mill to run out of balance. Experienced mill-men soon detect this. On account of this trouble, there is a difference of opinion as to the use of the baffle plates that are fixed to the return scoop plates in the mill.

The fine screens should be brushed once daily, if the ore is dry, and oftener if damp, with a wire brush. They last from 30 to 40 days, providing no stones escape and tear them. When the grinding plates get thin and nearly worn to the mantle plates, the mill requires re-lining. This is done in different ways; some mill-men prefer to have a spare set of mantles which are fixed to the plates at leisure. When the time comes for re-lining, these worn-out plates are taken out and the prepared plates fitted in; this requires about ten hours with six men. Others consider it best to leave the mantles in place, cutting off the old grinding plates and fitting on new ones as they proceed. This can be done in about the same time, but is awkward, heavy, and hot work inside the mill. There are several little points in ball-mill practice on which agreement will never be reached, but their effect is trifling. A No. 5 ball-mill, including foundations, may be erected for £600, and a No. 8 for £1000, bin and conveyors not included. It will usually cost about £300 per year for upkeep of a No. 5.

I have seen No. 4 size mills used in Broken Hill plants for wet-crushing jig middling that passed an 8-mm. screen; a No. 5 on the Lake View Consols crushing ore (sulphide), and the No. 5 at the Chaffers crushing the soft schistose oxidized ore. In the first instance I do not think the mills show great efficiency on such feed; in the second, the mill never had a real trial, as the grinding pans and tube-mills were already overtaxed; while at the last the ore is so soft that any comparison with stamps on hard ore can not be

Name	Number of Mills	Weight of Balls	Screens	Speed	Power	Drive	Capacity per day	Steel Consumption	Life of Grinding Plates
Associated	4 No. 8 6 " 5	4480 lb. 2240 "	30 by 30 25 " 25	27 r.p.m. 28 "	60 H.P. 25	Belt from shaft	80-85 tons 45 "	0.30 lb per ton	170 days
Associated Northern	3 " 5	2350 "	27 " 27	26 "	18 "	"	40 "	0.32 "	870 "
Chaffers	3 " 8	2800 "	27 " 27	25 "	20 "	"	40 "	0.74 "	180 "
Great Boulder	4 " 8	4480 "	30 " 30	24	60 "	" and friction clutch	80-90 "	0.64 "	105 "
Kalgurli	9 " 5	2200 "	26 " 26	25 "	25 "	Belt from shaft	40 "	0.45 "	300 "
Perseverance	8 " 8	4400 "	27 " 27	24 "	60 "	Motor & Belt	100 "	0.65 "	118 "
South Kalgurli	3 " 8 1 " 5	4480 " 2800 "	27 " 27	24 "	65 " 30	Motor & Belt	95-100 "	0.47 "	210 "

TABLE II

used. Some years ago the Eclipse mine had ten 900 lb. stamps crushing ore similar to that at the Chaffers at the rate of 10.5 tons per stamp per day through a 20-mesh screen; so the capacity of the Chaffers ball-mill of 93 100 tons through a 26 mesh is somewhat better than the 10 stamps. The wet mill product is:

Size.	Per cent.
+ 40	10.60
+ 80	16.12
+ 100	4.44
+ 120	3.56
+ 150	7.59
− 150	57.69

The ore is crushed in weak cyanide solution in the proportion of 1.6 to 1. The wear and tear in the wet mill is almost twice as heavy as in the dry, the grinding plates lasting 105 days.

Max Drott made some comparative tests on hard quartzite ores between a 5-stamp mill, and a ball-mill for the Krupp firm. The latter showed an output 40% greater than the battery, even the dry mill being better on the same ore. I am convinced that on a thorough trial, other things being equal, the ball-mill will show a greater output and efficiency than the stamp battery. Perhaps some one will take up this question and show that the modern heavy gravitation stamp is not the most economical crusher for its present work and that there are other machines that can do the work better. Some costs of ball-milling follow:

Pence per ton

Name	Wages	Power	Spares	Stores	Repairs	Sundry	Total
Associated.	6.45	13.78	6.73	2.67	0.49	---	30.11
Associated Northern	5.87	12.08	4.73	1.42	0.10	---	24.22
Chaffers.	2.09	10.64	---	0.25	6.88	1.71	21.57
Great Boulder	1.81	9.75	---	6.26	---	---	17.82
Kalgurli.	--	15.23	---	7.49	---	---	22.72
Perseverance	3.21	19.18	3.32	0.46	0.11	0.54	26.84
South Kalgurli	2.05	20.82	5.54	---	3.68	0.21	32.30

TABLE III

The methods of segregation of costs are not uniform, as will be noted at once. On some mines, spares, stores, and repairs are lumped together. Power costs are high on the Perseverance and South Kalgurli on account of the use of motor-driving. The Associated is in a state of transition from the old No. 5 mills to the cheaper run No. 8 size. The Great Boulder has lately installed a high-class steam engine, and it is expected to reduce power costs to the above figure. In table II above are given interesting details of ball-mill dry-crushing practice at Kalgoorlie.

QUARTZ can be fused in the electric furnace with coke and iron ore to produce ferrosilicon, which is employed in the manufacture of steel as a deoxidizer and to prevent the formation of blow-holes in steel ingots. Quartz may also be fused in the electric furnace to make tubes, crucibles, dishes, and other articles which can be used for certain purposes in the chemical laboratory instead of porcelain and platinum wares.

Briquetting Lignite

C. L. Wright has recently given, in Bulletin No. 14 of the Bureau of Mines, some results of experiments upon the briquetting of lignite. Three samples of lignite, one from Texas, one from North Dakota, and one from California, were made into satisfactory briquettes without the addition of a binder. It was proved that some lignites after having slacked by exposure can be made into briquettes without the use of binding material, notwithstanding a general opinion that this could not be done. Cohesion and weathering tests demonstrated that good briquettes endure handling and resist weathering much better than the lignite from which they are made.

The tests described apparently show that the cost of briquetting run-of-mine lignites with the German plant, which was used, would be from $1.35 to $1.75 per ton, according to the location of the plant. The cost per ton, loaded on cars, from a briquette plant at the mine should be, in Texas, $2.51; in North Dakota, $3.53; and in California, $5.24. It must be borne in mind that these figures are only approximate and are subject to wide changes because of local conditions. They apply to briquetting run-of-mine lignite to improve its heat value and weather-resisting properties, rather than to briquetting slack or waste coal. Since the tests have shown that at least some lignites slacked by exposure to the weather can be made into excellent briquettes, it may be possible to utilize lignite slack as well as bituminous slack and anthracite screenings for briquetting; the two latter materials having been made into briquettes on a commercial scale both in this country and abroad.

Of four samples of raw lignite, three samples contained about 40% moisture and had a fuel value of 6079 to 6241 B.t.u., while a Texas lignite, with a moisture content of 33% had a fuel value of 6840 B.t.u. The percentage of moisture removed in the process of briquetting ranged from 24 to 32%, and the heat value of the briquette was 36.5 to 54% higher than that of the raw lignites.

Excessive moisture in fuel not only causes a waste of useful heat during combustion, because the moisture is vaporized and the vapor superheated, but also is a source of expense to the consumer, who pays freight charges on useless water. For both these reasons lignite briquettes have the advantage over raw lignite. In the case of one of the North Dakota lignites the removal of 32% of moisture during briquetting permits a decided lessening of the cost of supplying a consumer with a given number of heat units. The superiority of the briquettes in this respect is of especial importance when transportation to a distant market is involved. If the briquettes possess no other advantage over raw lignite than their higher heat value, they would be worth 50% more than the raw fuel.

The Nippon Steel Works

By T. Haga

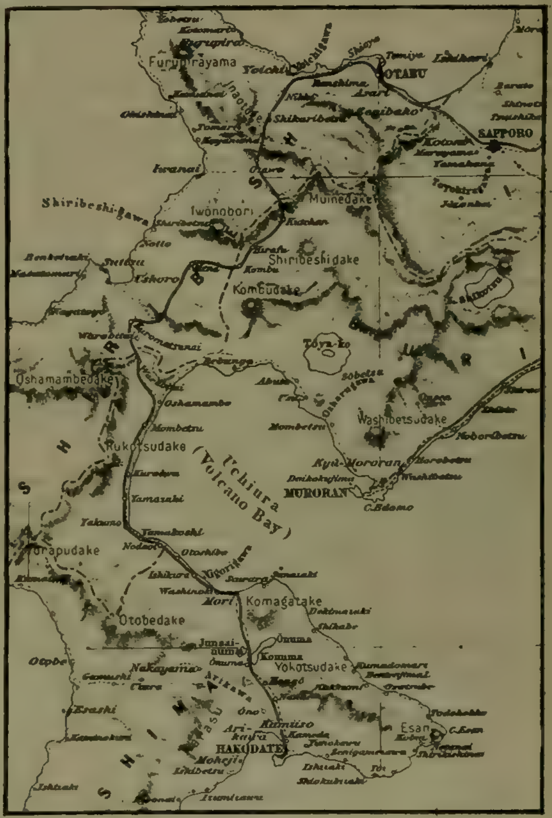
In a previous article I mentioned that the Government had introduced a bill in this session of the Diet to increase the capital of the Government steel works at Wakamatsu by 15,000,000 yen,* in order to check the importation of iron and steel. But since the people are dissatisfied with the yearly losses of the works, the bill was expected to fail to obtain the approval of the Diet. On the contrary, the Seiyukai, the leading political party, approved the bill under the pretext of a rapprochement with Government, so, contrary to expectation, the bill was passed after much discussion. As the present condition of the Government steel works was given in detail in my last article, I will now describe the newly established Nippon Steel Works, in Muroran, Hokkaido (Yezo).

To begin with, the effect of the Anglo-Japanese alliance gave rise to the establishment of the works with combined Japanese and English capital, so its establishment has international importance. When Government ownership of railways was undertaken in 1907 the whole length of railway under the control of the Hokkaido Colliery & Steamship Co. was purchased. This company, wishing to invest the funds thus received, applied for Government permission to establish an iron works. The Government was in no position to afford assistance, and the proposal was deferred. At this time Armstrong & Co., and Vickers, Son & Maxim, Ltd., were supplying the country with warships and ordnance, and had frequent consultations with the Government with regard to their inventions. These companies combined with the Hokkaido Colliery & Steamship Co. to gain Government permission to establish an iron works. As at this time the Anglo-Japanese alliance was concluded, the Government gave its consent to the starting of the enterprise upon a co-operative basis, considering that the co-operation of English and Japanese investors would realize effectually the objects of the alliance. Thereupon the representatives of the two companies met in Tokyo on March 7, 1908, and drew up a provisional contract, which was formally concluded in London on July 30 of that year, and on November 1 the first general meeting was held.

All the powers are endeavoring to improve ordnance and arms. Private individuals have also set up factories, so maintaining independence in case of war and also meeting the trade demands of other countries. Private enterprises are superior to Government enterprises in their use of capital, resulting in better equipment and plans. Nevertheless, in Japan, all war material has so far been supplied by the Government works, and private enterprises for the purpose have never been projected. Recognizing the tendency of the other powers, however, the Government has now come to recognize the necessity for private enterprise, especially in the iron industry.

The English and Japanese directors agreed upon the nomination of Vice-Admiral Yamauchi as adviser and obtained his appointment, which was afterward officially sanctioned by the Government. Thus the equipment of the foundry has come under the control of the vice-admiral. The foundry was established at Muroran, Hokkaido, for three reasons. First, this site belongs to the Hokkaido Colliery & Steamship Co. Second, it is accessible to coal mines. Third, there are ample facilities to accommodate the company and to lease the space for the navy and army departments. As Japan is not yet experienced in the iron industry, the skill of the Japanese metallurgists may be doubted, especially in view of the losses of the Government steel works at Wakamatsu. However, with the co-operation of the English there will be no cause for doubt. The army engineers have had wide experience in manufacturing of ordnance and iron-founding, have been in England and are acquainted with the English engineers. Moreover, most of the mechanics were formerly employed in the navy and were sent to England by this foundry to study the operation of iron works there. It is therefore believed that the enterprise will succeed. Some are doubtful because of the losses of the Yahata Government steel works at Wakamatsu, but the latter are under Government management and are devoid of promptness of action. As the Nippon Steel Works is under Government protection, no difficulties will be experienced. Some maintain that it would be better to engage foreign engineers and mechanics, but in this way the advantage of cheap domestic labor would be lost. It is sometimes necessary to employ foreign engineers and mechanics, but there is no need for this in daily work.

Prior to the establishment of the foundry the engineers inspected the iron works of Armstrong & Co. and Vickers, Son & Maxim, consulted with them personally, and obtained advice from the engineers in both the works, thus ensuring the newest designs. The construction work will be completed in August of this year.



MAP OF SOUTHERN HOKKAIDO.

The capital is 15,000,000 yen, fully paid, half of which is provided by each party. But as the whole works could not be completed with this amount alone, debentures amounting to 10,000,000 yen were issued. The total of 25,000,000 yen is to be spent for the whole establishment, 21,000,000 yen being expended in construction work. Besides the capital, 3,000,000 yen was advanced by the English interests until the issuing of the debentures, when the advanced money was returned. Deducting other expenditure for construction work to the value of 2,500,000 yen, there is a remainder of 4,000,000 yen which it is planned to use as working capital. In issuing the debentures, it was at first planned to entrust this to the English syndicate, but at that time, the close of the Russo-Japanese war, the money market in Japan was dull, owing to the universal business depression, which caused a panic among capitalists. It was therefore considered best to float the issue in Japan, and it was entrusted to the syndicate under the following terms: interest 5%, face value 95 yen, and the term of redemption five years.

---

*1 yen = 49.8c.

Ophir, Colorado

By A. L. Swenson

The town of Ophir, situated at an altitude of 9600 ft. above sea level, lies in a narrow valley that slopes gently for two and a half miles to Ophir station, on the Denver & Rio Grande railroad, thirteen miles south of Telluride. Except at this point, the valley is surrounded by high mountains, two of which are well known because of the numerous veins which have been found in them. These are Silver mountain on the north and Yellow mountain on the south of Ophir. The annual fall of rain and snow is heavy and the abundant moisture formerly supported a heavy growth of forest. Even now spruces and aspens cover the higher slopes, yielding to white pine and cedar on the flanks as the streams sink into canyons.

In 1876 ore was found on Silver mountain, but the prospectors were obliged to pack all their necessary supplies several hundred miles and then pack the ore out again to the railroad. Only the richest ore would stand this expense, yet it has been estimated that about $50,000 worth of ore was thus taken out during the first four years of the existence of the town of Ophir. In 1881 a railroad was built from Durango to Silverton, only fourteen miles from Ophir across the mountains to the northeast. A good wagon road was constructed from Ophir to Silverton by utilizing Ophir pass and the ore was then packed, on mules and burros, to the railroad at Silverton, whence it was shipped to the smelters.

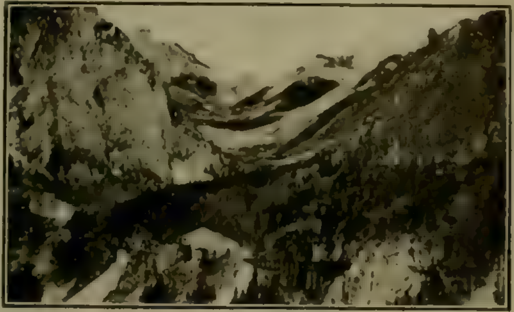
OPHIR, COLORADO.

The smelter returns for the next nine years show that ten and one-half million dollars worth of ore was shipped from Ophir; yet it was not until 1890 that the district attained real prominence. In this year the Rio Grande Southern railroad was completed to Durango and a station was built at the mouth of the Ophir valley. From this time on development of the district was very rapid, several mines were opened, mills erected, and gravity tramways constructed. In the fall of 1896 over 100 stamps were in operation in the town of Ophir, and nearly 500 men were employed in mining and milling the ore. The demonetization of silver caused almost all mining to cease in Ophir, as it did throughout the State of Colorado, and it is only lately that the district has started to recover from its slumber.

There is a striking relation between the physiography and the geology of the district. The mountains and valleys are the result of long continued erosion of a part of the San Juan volcanic plateau. The high peaks are all within the irregular diorite-monzonite stock which has been deeply scoured by the head-waters of several streams. Indisputable evidence of glacial action is found in the more elevated portions; this is especially noticeable at Howard Fork, where the rocks are finely polished and striated by the glacial movement.

The veins lie almost wholly in the diorite-monzonite stock. The fissured zones are from 3 to 6 ft. in width, the ore averaging about 2 ft. The minerals occurring in these veins besides gold and silver and classed as ores are galena, freibergite, polybasite, proustite, pyrargyrite, and stephanite. The non-metallic gangue minerals are quartz, calcite, siderite, dolomite, fluorite, barite, sericite, biotite, chlorite, apatite, orthoclase, and kaolinite. The metallic gangue minerals are pyrite, chalcopyrite, zincblende, mispickel, magnetite, stibnite, and native copper. The silver is in the galena and freibergite, while an increase in copper pyrite is often accompanied by an increase in the gold.

In places the veins swell, forming chambers of ore, which have the character of angular breccias of country rock cemented by ore. Such veins occur in many of the mines on Yellow mountain. With the silver-bearing veins there occur veins of auriferous quartz having different physical characteristics. They consist of white quartz of saccharoidal nature, with disseminated fine-grained auriferous pyrite and free gold. The Badger vein on Silver mountain is of this character, and on Yellow mountain a similar vein lies parallel to and within a few feet of a vein carrying almost silver ore alone. In several instances the veins swell or widen on the steep dips and pinch where the dip is flatter. Such occurrences are indications of a normal faulting along the fissures, that is, a downward movement of the hanging wall with reference to the foot-wall or vice versa. Had the faulting been reversed, the portions of the vein would have been on the flat dips, in the narrow places, or along the steeper dips. Lateral faulting of the veins occurs where the ore of one vein is distinctly cut by that of another.



OPHIR VALLEY.

Yellow mountain is a gabbro-diorite stock, from which andesitic and rhyolitic rocks have been denuded. On its flank the Jura-trias sedimentaries are exposed, standing at an angle of 45°, thus proving that there need be no apprehension of a change of formation in depth. This is further proved by the fact that the Carribeau mine has been worked to a depth of over 1200 ft. without finding any change. The veins on Yellow mountain are well defined fissures, varying in width from 3 to 10 ft. between the walls; the general course of the veins is N.80°W., with two exceptions, which strike nearly due east and west. The two chief mines on Yellow mountain are the Carribeau and Silver Bell, both of which have been large producers, and each possessing its own mill. That of the Silver Bell is situated within a few hundred feet of the railroad station at Ophir Loop, and is connected with the mine by a tramway. The equipment in this mill, of a capacity of 150 tons per day, consists of 50 stamps, 20 Frue vanners, 3 Wilfleys, 1 jig, and the necessary crushers. To the east, 4000 ft. away, is the 30-stamp Carribeau mill, which is operated by water-power. The Silver Bell mill was formerly run by steam, and from now on will be run by electric power generated by the Telluride Power Company.

The sedimentary rocks on Silver mountain are highly metamorphosed by the diorite-monzonite which underlies the valley, and also by the dikes which cut them. These dikes are the mineralized zones of the lower formation. There are two main sets of vein fractures, the older set strikes north and south and the younger east and west. The Belcher and Schumacher veins strike northeast and are the only two productive veins, so far discovered, which do not belong to either series. The Crown vein is the most characteristic one and has a length of 4500 ft. with a dip of 16° north. Its width varies from 2 to 12 ft. and carries good ore throughout its entire length. The Schumacher vein dips 5° northwest and intersects the Crown vein in the Osceola mine. Its general direction is N.45°E. Parallel to the Schumacher vein lies the Belcher vein, which intersects the Crown vein in the centre of the workings of the Crown mine.

The most important and persistent of the north-south veins is the Suffolk-Gold King, which has been worked through several adits on both sides of the mountain. To the west of the Suffolk vein lies the Yellow Girl, which unites with the Suffolk at a depth of 750 ft. Prospects exist on all of these veins and all have produced ore, but the steady producers on Silver mountain are the Carbonero, Suffolk, and the Calumet-Telluride mines. The Suffolk mill develops its own water-power and contains 40 stamps, 4 Wilfley tables, 2 Frue vanners, and 5 Pierce amalgamators, in addition to the crushers.

The Calumet-Telluride mill, of 30 stamps, is the only mill at Ophir developing its own water-power. The electric equipment consists of one Allis-Chalmers generator, three single-phase transformers that reduce the original 6600 volts to 440, and one transformer that reduces the 440 volts to 220 and 110 volts for lighting purposes. There are two 30-hp. Allis-Chalmers induction motors and one 7½-hp. Bullock motor.

In addition to the mines already mentioned there are the Favorite, Gold Crown, Badger, Red Jacket, Montezuma, Nevada, and many other prospects in various stages of development. During the past winter the Carbonero and the Carribeau mines have been the steadiest shippers, but nearly all the mines are now working and several improvements are being made that will materially increase the production of the camp. All the mines have large bodies of ore that vary in value from $2.50 to $60 per ton, not to mention the large tonnage of ore on the dumps of the old workings that averages $8 per ton. Experiments recently conducted by the management of the Carbonero and Suffolk mines show that by the use of modern methods of ore-handling, all of this ore can be landed at the station at a cost of about $2 per ton, which will leave a good margin of profit, and undoubtedly the next few years will see the town of Ophir again a thriving mining camp with a large daily production.

Miners Phthisis on the Rand

After making several futile attempts to deal with the miners' phthisis question in the Union Parliament, temporary measures have at last been adopted, and a commission has been appointed to enquire into and report upon the extent to which the disease exists, the degree to which miners become incapacitatd when suffering from the disease, and the number that may annually become incapacitated. With this information before them, the members of the Union Parliament should be in a better position to deal with the matter than appeared to be the case during the recent parliamentary debates. So urgent does it appear to the Union Parliament that some compensation should become immediately available to those suffering from the disease, that the Government also has appointed a Board to distribute the necessary allowances. The maximum allowance for any individual sufferer is fixed at £250, or an annuity can be granted for a period not exceeding two years which may be paid weekly or monthly, but must not exceed £105 per year. A list of mines to which the Act applies is also published, and it is interesting to notice that only the mines on the Rand and in the Heidelberg district are included. Those in Klerksdorp, Lydenburg, Barberton, and other parts of the Transvaal, as well as the coal and base-metal mines do not come under the Act. The Board is authorized to call upon the mines appearing in the *Gazette*, as previously mentioned, for payment of £25,000; each mine to pay in proportion to the number of white persons employed during the past two years, the numbers being furnished to the Board by the Government Mines Department.

Fluorspar in New Mexico

By Ernest F. Burchard

[*]The occurrence of fluorspar in southern New Mexico has been known for some years, several specimens of the mineral having been sent from Silver City to the mineralogical museum of the New Mexico School of Mines at Socorro, within the last ten years. Only recently, however, has fluorspar been found in quantities sufficient for exploitation. The American Fireman's Mining Co., of Kansas City, Missouri, in prospecting for metallic ores on property situated 10 miles northeast of Deming, Luna county, New Mexico, has opened a number of veins of fluorspar, which give promise of containing nearly, if not quite, sufficient spar to supply the Western market for several years.

The fluorspar here occurs on the flanks of a hill called 'Fluorite Ridge,' one of the foothills of Cooks range, that rises about 1350 ft. above the plain at Deming. The most promising prospects have been opened in two places about 1¼ miles apart. One of these is at the extreme southwestern base of the ridge on a gentle rise about 400 ft. above the plain; the other well up the south slope of the ridge about 900 ft. above the plain. Two railways pass through Deming, the Deming & Silver City branch of the Atchison, Topeka & Santa Fé railway, and the San Francisco and New Orleans line of the Southern Pacific. A third road, the El Paso & Southwestern, makes Deming a terminal point.

Wagon-roads radiate in all directions from Deming, which has of late become an important business centre, largely on account of the development of the underground waters of the Mimbres valley and their utilization in agriculture. Deming lies in a nearly flat valley covered by desert deposits, with Cooks range 10 to 15 miles northeast and the Florida mountains 10 miles or more to the southeast. The fluorspar deposits are most easily reached by a 10-mile drive from Deming, but the product is shipped from a siding on the Atchison, Topeka & Santa Fé railway, called Mirage, 5½ miles southeast of the prospects.

Fluorite ridge consists of a central mass of monzonite-porphyry which has intruded strata of Paleozoic and Mesozoic age, chiefly Ordovician limestone and Carboniferous and Cretaceous sandstone, quartzite, and conglomerate. The dip of the sedimentary strata on the south and west sides, where the fluorspar is found, is very steep, even vertical, and masses of the strata have not only been tilted up by the intrusive action but folded into the igneous rock. The base of the ridge is surrounded by an agglomerate, consisting of angular masses of andesite imbedded in tuff. Some thin dikes of basalt cut the agglomerate, and unconsolidated 'desert fill' overlies it at a short distance from the base of the ridge.

The fluorspar occurs in veins cutting altered monzonite-porphyry. Certain of the veins fill fractures in the rock along which there has been movement in both a vertical and horizontal direction, but between the walls of other fissures there has not been any noticeable displacement. The rock at the southwest base of the ridge is cut by two or more groups of approximately parallel veins. As shown by the prospect openings, there appear to be at least 5 or 6 distinct veins in each group. One group of veins strikes N. 17° E. to N. 27° E., and the other strikes N. 6° E. to N. 18° W., while other veins were observed to strike at various angles between these limits. The veins are nearly vertical or dip steeply in a southeast or northeast direction. The vein material is mainly fluorite, mixed with a little quartz. Where the veins are partly silicious they resist weathering slightly better than the surrounding porphyry, and therefore leave broken traces on the surface. At the surface the fluorspar is altered in places to calcium carbonate. The thickness of the veins as shown by surface cuts and by prospect pits and shafts, ranges from a few inches up to 12 ft. or more, but it is generally from 2 to

---

4 or 5 ft. The structure of the veins is in places distinctly banded, in other places the vein may appear to consist mainly of a mass of crystalline spar, showing no banding but carrying pockets of quartz, and brecciation of the vein, by which large fragments of the wall rock have been included, is by no means uncommon. The walls of the veins, where open to any depth, are found to be smooth in places, but are rarely smooth or regular for many feet, and the wall rock is generally much decomposed.

At the locality on the south slope of the ridge only one set of veins, striking in a northwest direction, was observed. They stand nearly vertical, or dip steeply toward the northeast. These veins had been opened in only two or three places in 1910, and the maximum width observed was only about 4 ft., not all of which was spar. The veins cut monzonite porphyry, as at the first locality, and were observed to outcrop at intervals in the direction of the strike for a distance of one-quarter mile.

At the place first described the American Fireman's Mining Co. opened in 1909 a number of the veins by means of shallow cuts, and has sunk several test pits to depths of 6 to 12 ft. and two shafts to depths of about 80 ft. In all about 20 openings had been made up to August 1910. A triangular area about one-fourth mile wide at base from northwest to southeast, and about one-third mile from northeast to southwest has been shown to carry productive veins of fluorspar. The surface of the area slopes gently toward the southeast. At the main opening the vein strikes N. 17½° E. to N. 22½° E., and dips 65 to 70° toward the southeast. The vein had been opened to 75 or 80 ft. in August 1910, and had been worked underground to a distance of about 100 ft. on the strike. The thickness between the walls of the vein measures 4 to 12½ ft., the irregularities being due to pinching together of the walls in places. The strike of the vein is apparently slightly sinuous according to the irregularities in the walls, but there are no evidences of movement between the walls. The rock inclosing the vein is altered to a reddish color, so far as observed, and although the vein walls are smooth and clean in places, in others there is interpenetration of the vein and wall material.

The fluorspar is usually of a light-green shade, but there is some purple spar present, especially near the margins of the vein, and some quartz is present in pockets and thin stringers scattered throughout the mass of spar. The spar is mined from several levels, and milled down through chutes to the lowest level, from which it is hoisted in buckets up the shaft to the surface. A steam hoist was being installed in August 1910. On the strike of the opening, less than 100 yards to the north of the shaft, an open-cut and shallow burrow showed a promising vein of spar with a fork extending in a northwest direction. These veins, and one other a few yards to the west, are the nearest to the limestone mass, which lies 35 yards or more to the west. None of the veins was observed to extend into the limestone. The greater part of the spar that has been produced in this region has been taken from the shaft just mentioned.

The other veins that have been opened here lie 250 to 325 yards west of and at a lower level than the principal shaft. Eight or ten shallow trenches and one test-pit about 30 ft. deep have been dug, exposing veins 6 in. to 4 ft. thick, containing good fluorspar in places and running into barren or highly silicious material in others. Some of these veins strike a little west of north, and others strike N. 30° W. to N. 42° W. Nothing sufficiently promising seems to have been found here except at a point about ¼ mile north of the company store, where a good vein of spar has been developed by a series of trenches, pits, and a shaft. There appear to be two or three veins here nearly parallel and only a few yards apart. The main vein seems to follow a fault-plane as indicated by openings extending 100 yards or more. At the deepest place the workings are about 75 ft. below the surface. The surface cuts are extensive and show the structure fairly well. The foot-wall of the vein is a cherty conglomerate, resembling the material capping the ridge ¾ mile west. The hanging wall is so covered with spar that it is difficult to determine its nature. When the spar has been removed, the wall is shown to be surfaced by soft clay so that a thin layer of spar is generally left to prevent caving. The indications at the surface are, however, that the hanging wall is of agglomerate. In places west of the fault, or beyond the foot wall, loose fragments of reddish granitic and porphyritic rock were noted on the surface. The fault hades toward the hanging wall, which is on the upthrow side. Just to the north of the shaft the strike of the vein has been so bent that for 3 or 4 ft. the fluorspar has been offset and cut out entirely. At this point the walls are much slickensided in a nearly horizontal direction. There is general evidence of faulting here since the vein material was deposited. The outcrop of the vein has been repeated, and a small section of it that had been shoved over to the west 10 ft. or more was at first thought by the miners to be another vein, but it was soon discovered that it played out at shallow depth. In the main vein here the opening showed from 1 to 7 or 8 ft. of good quality fluorspar, and a considerable tonnage has been mined and some shipments have been made.

MAP OF NEW MEXICO.

At these prospects the fluorspar is not subjected to any mechanical concentration, but is simply cobbed and stacked up in piles of lump and gravel spar from which shipments are made. The spar is hauled by wagons 5½ miles to Mirage, a station on the Atchison, Topeka & Santa Fé railway, over a road that is down-grade for a mile or more and then nearly flat. At the base of the grade is a platform scale on which all the shipments are weighed. For several miles the road is rather sandy, making the hauling of heavy loads difficult. In 1910 G. M. Sadler, of Deming, succeeded the American Fireman's Mining Co. in the operation of the prospects. A series of analyses is given below which shows the general excellence of the spar that has been mined from this district.

At the second locality mentioned, about 1¼ miles northwest of the locality just described, Mr. Sadler has opened by surface cuts a few veins of fluorspar. The openings are within 200 to 250 ft. of the summit of the ridge, and are on rather a steep slope facing south. The principal opening is on a nearly vertical vein that strikes north to northwest, bending toward the west as it is driven farther. In August 1910, this opening extended about 100 ft. and reached a depth of about 15 ft. at the extreme end. As opened, the vein ranges in thickness from less than 1 ft. to more than 4 ft., but the maximum thickness is sold as fluorspar. The spar is streaked with silica and iron oxide, and shows quartz druses and geodes, and some crushed brown [illegible] seams and pockets, but in places there are quite pure masses of apple-green colored spar. The spar on the dump was [illegible] green, and pockets [illegible] mineral with hard clay and ferruginous material. Another [illegible], whose [illegible] varies [illegible] the vein at a slightly lower level, has exposed for 200 ft. or more a vein showing [illegible] at 12 to 18 ft. thick, which is largely [illegible]. The spar where the surface is [illegible], but the [illegible] is [illegible]. No spar had been shipped from this vein up to August 1909, although preparations were being made to ship some material from the largest [illegible]. A [illegible] at which spar is weighed in wagons has been built along the wagon-road to facilitate the loading of wagons.

Fluorspar or fluorite, chemically calcium fluoride (CaF_2), consists of calcium and fluorine in the proportions of 51.1 to 48.9. The mineral is crystalline, and slightly harder than calcite. It crystallizes in the isometric system and is found commonly in cubical crystals. In color the spar ranges, according to purity, from a clear, slightly tinted or green glass-like substance through various other tints and colors to dark purple, although most of it is white and [illegible]. Fluorspar, associated with other minerals, has a wide distribution geographically and a wide range geologically. The deposits thus far exploited in the United States are, however, confined to the following Territories and States: Arizona, New Mexico, Colorado, Illinois, Kentucky, and Tennessee. It is used in making glass, enameled and sanitary ware, in the electrolytic refining of antimony and lead, the production of aluminum, the manufacture of hydrofluoric acid, and in the iron and steel industries, in which it is used as a flux in blast furnaces and in basic open-hearth steel furnaces. It is estimated that about 80% of the American fluorspar output, largely in the form of gravel spar, is consumed in the manufacture of basic open-hearth steel. The use of fluorspar is increasing in practically all of these industries. The Western market for fluorspar is more limited than that of the Central and Eastern States, but it is nevertheless increasing. During the last year new iron and steel works have been opened at Irondale, Washington.

Supplies of spar mined in the West have not heretofore been sufficient to supply the Western market for more than a few months at a time. This has been due to several conditions, the most important of which is that the Western spar thus far produced has not been of as high a grade as that produced in the Illinois-Kentucky district. Fluorspar for iron and steel making should carry at least 85% calcium fluoride and preferably it should be purer. For most other chemical uses it should contain from 95 to 98% calcium fluoride.

None of the spar mined in Colorado and New Mexico has been cleaned in any way except by hand. Mechanical concentration would improve the grade of the Colorado spar greatly, but none of the fluorspar producers in Colorado have proved it sufficiently profitable to warrant the erection of washing plants. In certain cases water is available, but in others the problem of finding water would be difficult. The Colorado product has been [illegible] high enough in grade to make [illegible] to producers.[1] In the case of the deposits near Deming there is little necessity for washing the spar on account of the natural purity of the raw material. Doubtless a considerable saving of spar might be accomplished by washing, but such a process would not be at all feasible on account of the scarcity of water. The supply of water for men, teams, and the hoisting engine has to be hauled from a well more than four miles distant on the road to Deming. There is little probability that a well could be obtained by drilling anywhere near the fluorspar deposits on account of the nature and structure of the underlying rocks.

The following table gives analyses of gravel fluorspar from Mirage, New Mexico, in carload lots used in basic open-hearth steel furnaces, and analyses of spar from Colorado, Illinois, and Kentucky, made on a similar basis, are given for comparison. These analyses were all made by the Colorado Fuel & Iron Co. except the last, made by the Carnegie Steel Co., and the two preceding this, by the Lackawanna Steel Co. These two samples contain 1.08 and 1.22% of $MgCO_3$, respectively; the others have but a trace.

Fairview, Ill.	88.85	5.4	1.45	..

From these analyses it may be seen that the spar shipped from Mirage is of an exceptionally high grade, considering the fact that it has not been washed and cleaned as has the Illinois-Kentucky product. Mining is here done almost wholly by contract. Mexican labor is employed, and miners can earn about $1.50 per day. Mining the spar costs $1.75 per ton, plus 25c. for incidental expenses, and haulage to the railroad costs $1.50, making a total cost of $3.50 per ton loaded on cars. The spar in 1909 sold for $5.25 per ton on the cars, based on at least 90% calcium fluoride, the freight from Mirage to Pueblo paid by the purchaser was $2 per ton. According to contract, a penalty of 20c. per ton is deducted for each per cent that the spar falls below 90% calcium fluoride, but no premium is paid unless it carries more than 95% calcium fluoride, when each unit brings 20c. more per ton. The equipment for mining the spar is simple, the largest item of expense being a small steam-hoist stationed at the deepest working. Several teams are necessary to haul the output. Small stone buildings and machine-shops have been constructed at both mines where the spar is being developed. The laborers live in tents, and work can be carried on the year round. From the opening of these deposits in the summer of 1909 to the close of 1909, nearly 5000 tons of fluorspar had been shipped, averaging 92% calcium fluoride. The exploitation and development of fluorspar deposits under present conditions in the Western States cannot be said to offer great inducement; nevertheless, the market for fluorspar is growing, and where deposits are found so situated that the freight rates do not hold down the return to a profitless level and where the cost of haulage does not eliminate all chances of gain, the development of such deposits should be encouraged.

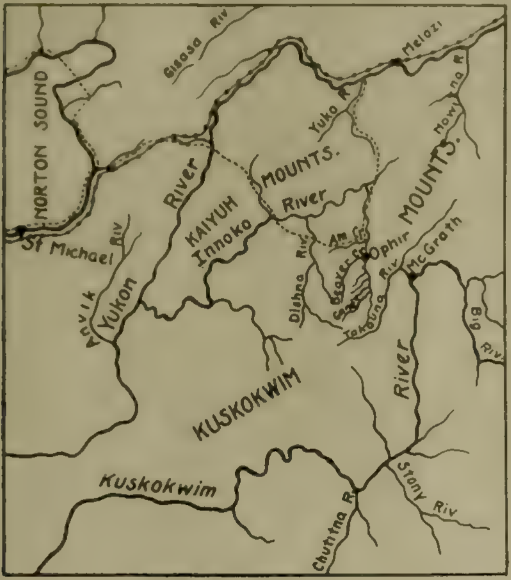
Kuskokwim River

By H. W. Reath

The Kuskokwim river is approximately 1000 miles long, being the second in size of Alaskan rivers, and is navigable for about 800 miles with light-draft steamers. Placer gold is found on every tributary from the mouth to its head-waters. In the last four years I have explored and prospected the Riglugalic river, the largest tributary on the south side. This stream empties into the Kuskokwim about thirty miles above Bethel. Slate is most common, but every type of rock characteristic of a mineralized country is found here. The principal minerals already found are gold, silver, and antimony, together with traces of platinum, tin, and tungsten. The quartz veins are, as a rule, wide and well defined, and can be traced for miles. At one place a bed of blue gravel occurs that looks like the pulp from a stamp-mill. I panned some of this and got a quantity of iron sulphide, assaying 1 oz. gold and $13.46 silver per ton. Without any doubt this has been ground down by glacial action from some large orebodies in the vicinity. This bed of gravel was covered by a blanket of fine blue clay about 1 ft. thick, which looked like settled slime. A sample from a place between patches of snow assayed $111 in gold, silver, and antimony; another sample taken for a width of 100 ft. assayed $8.68 in gold and $1.30 in silver.



MAP OF THE KUSKOKWIM.

Placer mining has been done in a small way on the Tuluksak river, thirty miles above Riglugalic river, and in the last two years about 1500 oz. gold was taken out; this gold is coarse, and in shape like a pumpkin seed. Two miners went outside last fall, taking along seven pounds of gold dust from the Tuluksak; but no gold has been taken out on the Riglugalic yet. The gold found on this river is fine and evenly distributed through the gravel; this is ideal for hydraulic mining, as there is sufficient grade in places and an abundant amount of water the whole season. Perhaps there is some good dredging ground, as good prospects can be found on the bars along the river, and there is a large area of auriferous gravel beds and ancient channels which the river has cut, exposing the bank of gravel about 80 ft. deep with a bottom about 12 ft. above present water-level. This could be worked at a cost of 4c. per cubic yard by hydraulicking. Ten miles south is the Quisluck river, where there is also placer gold. Nearly the same distance south is the Eak river, where there is reported to be placer gold. About forty miles south of Eak river is a small river, which empties into Kuskokwim bay about five miles below Quinhagamut, some prospectors there took out a few hundred dollars worth of gold dust last fall. Provisions are not unreasonably high at Bethel. Flour sells for $6 per 100 lb., butter, $1 a roll, bacon, 1 lb. for $1, beans and rice, 10c. per pound. Freight charges on goods from Seattle laid down on the river bank at Bethel are $30 per ton, and from Bethel to Golden Gate Falls by reindeer from $40 to $100 per ton. There is no need of a rush into this country because there will be found just as good mines ten years from now as at the present time. Whoever intends to come here should prepare to stay at least for two years. The gold is here, but it takes time to find it. The best time to come is about August 10, when the mosquito season will soon be over and there will be time to get settled for the winter. Good vegetables are raised along the river, and there are plenty of wild berries, which make excellent preserves. I believe beef cattle would do well here, as there is good grass along every river in the country. The river breaks up some time between May 1 and 15, and freezes over about October 15. Seventy-five working days in the season, as an average, can be counted on, according to my field notes. I had the pleasure of meeting last summer Major Richardson, the chief of the Alaska Road Commission. He is doing excellent work which will aid a great deal in developing the country and giving the prospector better facilities. The Northern Commercial Co. sent in a river steamer last summer and it is hoped that others will be sent.

Butte Copper Production

The copper production of the Butte mines for June is estimated at 22,691,200 lb., as against 21,720,770 lb. for May, and 21,156,150 for April.

The monthly yield of the Butte mines since the first of the year is shown below, with comparisons:

	1911.	1910.	1909.
January	22,172,930	19,224,250	26,502,600
February	20,697,320	13,755,620	24,871,730
March	21,522,060	24,575,700	28,077,510
April	21,156,150	25,087,200	25,347,420
May	21,720,770	28,363,760	26,443,240
June	22,691,200	26,356,200	25,187,784
July	....	24,303,500	26,580,820
August	....	24,762,800	26,061,140
September	....	22,990,050	26,584,180
October	....	22,913,781	28,166,160
November	....	23,636,550	27,649,144
December	....	22,564,125	14,675,880
Total	....	278,715,536	306,147,616

The daily record for June, showing tons of ore mined daily, pounds of copper per ton of ore, and total pounds of copper produced for the month, is shown in the following table:

	Tons ore mined daily.	Lb. Cu per ton of ore.	Lb. Cu total.
Boston & Montana	3,400	63	6,426,000
Anaconda	3,800	60	6,840,000
Butte & Boston	440	61	805,000
Washoe	300	60	540,000
Trenton	420	39	743,400
North Butte	900	61	1,647,000
Butte Coalition	870	70	1,827,000
Tuolumne	180	112	604,800
East Butte	360	90	972,000
Original	1,100	62	2,046,000
Miscellaneous	100	80	240,000
Total	....	..	22,691,200

As the average monthly production during 1910 was a little more than 23,000,000 lb. and in 1909 was slightly over 25,000,000, it is seen that the monthly production for the first half of this year has been 2,000,000 lb. less than last year.

Deep-Level Ores of the Rand

By An Occasional Correspondent

The question of permanence in the Rand Main Reef series has been reopened by C. O. Schmitt in a paper read by him before the Institution of Mining and Metallurgy in London at a time when many investors are viewing the continued decrease in grade with no small measure of anxiety. Mr. Schmitt's contribution was entitled 'Future Economies in Rand Production Plants', but, as pointed out by H. F. Marriott, of Wernher, Beit & Co., the title of the paper by no means indicates the wide scope of the subject-matter. For a number of years the future of the great deep-level mines of the Witwatersrand has been a theme for discussion, and the lessened yield per ton of the Rand today, when the deep-level areas are contributing such a large proportion of the output, compared to the epoch of outcrop mining, signifies to many that the conglomerate deposits become impoverished as greater depth is attained. The technical champions of the industry in London have, of course, taken up the cudgels on behalf of the view that the Rand is not in reality becoming poorer in depth, but that the reduction of the cost of operation has brought huge quantities of ore within the zone of profitable working, and that as a result the amount of ore available for milling has been increased at the sacrifice of value per ton. This is exactly what has happened, and although it has been shouted from the house-tops by directors, engineers, and managers for so long, it is still apparently the case that the public at large, and not a few mining engineers in particular, believe that the Rand in depth is but a bit of reflected glory of the Rand in the epoch of outcrop workings. H. F. Marriott has sharply discussed that portion of Mr. Schmitt's paper which touches on this all-important matter, and, backed as he is by years of South African mining experience, and a formidable array of facts and figures, his views are fully entitled to respect.

There can be no doubt that the basis of comparison between earlier and present-day Rand returns is erroneous, and that the results obtained in outcrop mines, chiefly from the Central Rand in the nineties, were misleading and quite unrepresentative of the field as a whole. Selective mining was naturally carried to a wholesale degree in those days. All the world over, the richest portion of the outcrop is first exploited, and the Rand is not an exception to this rule. With deep-levels the case has been vastly different, and even if it were desired to select rich sections (which in these days, when the Rand gold mining industry is run as a sound and enduring business, is not desired) it would be impracticable to avoid the sinking of deep verticals into zones of variable value. Of the many deep-level shafts sunk on the Rand during recent years, a number have intersected a medium-grade section, a number have cut the reef in an impoverished region, while others have struck high-grade ore. As a result of the extensive developments carried out from these shafts, vast amounts of low-grade rock of small value have been exposed and are included in the ore reserve. The central portion of the Rand, with one or two rich zones of restricted area on the eastern and western extensions, has been mainly responsible for all the fiction that has been circulated regarding the departed glory of the Main Reef Series. The outcrops of the Robinson, the Ferreira, and the Wemmer mines were of abnormal richness, but when the first few hundred feet was worked out there was but little to choose between their lower levels and the Robinson Deep, situated on their dip. It should, moreover, be remembered that there are numerous instances of deep-levels containing higher-grade ore than the outcrop. In so far as the central section of the Witwatersrand is concerned, the City Deep has proved a higher-grade mine than the City & Suburban; and the Village Main Reef is a richer mine than its outcrops, the Jubilee and Salisbury, have been.

The sum and total of H. F. Marriott's investigations is, that taking the Rand as a whole, the deep-level areas are of the same grade as the outcrop section over the whole length of the conglomerate formation, and it may be stated that Wernher, Beit & Co.'s engineer has not arrived at this conclusion without a very full and thorough investigation and the examination of much statistical data.

It is of interest and importance to note that H. S. Denny, who was for long associated with the General Mining & Finance Corporation in Johannesburg, holds a similar opinion, and in the discussion of Mr. Schmitt's paper, stated his case in plain and lucid terms, submitting interesting tables bearing on hypothetical cases assuming blocks of different values at different milling periods, which demonstrated that the mining industry has merely risen to the exigencies of the situation, and that, although the days of the small stamp-battery, ounce-to-the-ton rock, and high costs are over, a longer and more enduring period of far greater stability has been begun.

Washington Workmen's Compensation Act

This new law, which will go into effect on October 1, covers workmen in quarries, mines, smelters, and powder works, as well as in other lines of industry. The State has appropriated $150,000 for administering the law, and the Governor has appointed a commission composed of George A. Lee of Spokane, representing the legal profession, chairman; G. A. Pratt of Tacoma, for the manufacturers and employers; and J. H. Wallace of Seattle, for the workingmen. Some of the advantages claimed for the new law are that it gives adequate protection for employer and employee, increased safety of industrial operations, sure and certain relief for workers injured at extra-hazardous occupations, and their families and dependents, elimination of litigation, and consequent saving of retainer's fees and court expenses, and the regulation by State police powers of dangerous trades.

The law provides that each industry in the State shall contribute a certain percentage of its pay-roll to an accident fund, from which various sums are paid for total or part disability or on death to the family and dependents of the injured workman. The expense of handling the fund will be borne by the State. Injured workmen, their families or dependents cannot recover by law except where the injury is caused by the intent of the employer, in which case the workman or his family may recover not only the sums due under the new law, but also may sue for any excess of damage over those amounts. Where a workman is injured because the employer has neglected to observe the safeguards required by law or by the regulations of the department, the employer must pay 50% more than the fixed amounts. Should the workman intentionally injure himself he will receive no benefit.

The industries of the State are classified and certain premiums fixed for each class. The employers are required to pay three months premiums into the State treasury on or before October 1. After December 31, monthly payments are required; provided, however, that if any industry has a sufficient amount on deposit with the State to take care of its accidents no further payments shall be required. Each industry is responsible only for the accidents occurring in that class. It is intended that the accident fund shall be neither more nor less than self-supporting. The rates are subject to readjustment, depending on the number of accidents and the need of compensation of injured workmen.

Employers are required to report accidents promptly, and their books, records, and pay-rolls must be open for inspection by the commission. Refusal to permit inspection is made a misdemeanor and the employer also is penalized $100 for each offense, to be collected by action in court and paid into the accident fund. Misrepresentation in his pay-roll makes the employer liable to ten times the difference between the correct and the wrong figures. If the employer refuses or fails to pay his monthly assessments, a workman injured in his service may sue in the courts with the employer's defenses of 'fellow-servant,' 'assumption of risk' and 'contributory negligence' abolished. No part of the premiums can be deducted from the wages of the workmen, any violation by the employer of this section of the law being made a gross misdemeanor, punishable by one year in the county jail or by a fine of $1000 or both.

The schedule of payments for various injuries is as follows: In the event of death, expenses of burial, $75, payments to widow or invalid widower, $20 per month while unmarried, $240 in a lump sum on remarriage of the widow; for each surviving child under 16 years, $5 per month, monthly amount limited to $35. If no widow or widower survives, $10 per month to each child under 16 years. The same rule applies to children who become orphans by death of surviving parent, with monthly limit of $35. Dependents will be paid 50% of the average monthly support formerly received from the deceased workman, limited to $20 per month. Parents of deceased unmarried workman receive $20 per month up to time he would have been 21 years of age. When totally disabled, loss of both arms or one leg and arm, sight, paralysis, or other injury preventing the workman from doing any work, entitles him to $20 per month if unmarried, if supporting wife or invalid husband, $25 per month, if the husband is not an invalid, $15. For each child under 16 years, $5 per month additional up to a total of $35. In case of death of the totally disabled workman, the widow or widower receives $20 per month until death or remarriage and $5 per month additional for each child under 16 years. Orphaned children receive $10 per month.

When partly disabled by the loss of a foot, leg, hand, arm, eye, or fingers, the workman will receive a certain cash lump sum up to $1500. The loss of one arm at the elbow is made the maximum injury, and the payment for other injuries is scaled down by the commission. If the injured workman resides or moves out of the State the commission may lump the monthly payments, not to exceed $4000, based on the American mortality table. Any decision of the commission is subject to appeal in the superior courts. Howard L. Hindley, secretary of the commission, says that it is thought the new system will create a better feeling between the employer and the employee, and in the end establish the principle of State industrial insurance on a sound and practical economic basis.

Cyanamide in America

There are now twelve factories engaged in the manufacture of cyanamide (lime-nitrogen), and one or two others in the course of construction, with an aggregate present and projected capacity of about 250,000 tons. These factories are scattered throughout Europe, with the exception of the American Cyanamid Co. at Niagara Falls, Ontario. The American company, which has been operating since January 1910, now has a capacity of approximately 13,000 tons a year. The product is somewhat more highly developed than much that is produced abroad, due to the requirements of the American market that it shall be capable of being compounded into complete fertilizers. The free lime, which constitutes a considerable percentage of 'cyanamide,' is hydrated; and it also undergoes a further treatment to eliminate to a large extent the dust nuisance which was so objectionable in the original product.

The plant at Niagara Falls is of a most substantial character, the buildings being entirely of concrete and steel, even to the roofs. Power is the chief single item of expense, and as the factory runs every minute of the day, 365 days in the year, it must be obtained continuously and cheaply. The process as followed by the American Cyanamid Co. consists of the making of calcium carbide, which is pulverized and treated in electric ovens with nitrogen gas under pressure. The nitrogen gas is derived from the atmosphere, by a modification of the well known copper process. The American Cyanamid Co. is, with one or two exceptions, the only cyanamide factory which does not use the liquid air process for the manufacture of its nitrogen. —*Jour. of Ind. and Eng. Chem.*

Portable Powder Thawer

When a large amount of drilling and blasting in the field is to be done, the problem of handling the necessary powder becomes important. This is particularly true where the temperature is so low that the powder must be thawed before using. In the California dredging fields it is occasionally necessary to loosen up hard ground ahead of a dredge; and the same condition frequently arises in placer work. The magazine or powder-house shown in the accompanying illustration, designed by Charles Helman, of the El Oro Dredging Co., was to meet these conditions. The magazine is built of wood, with sawdust-filled walls, and is covered with galvanized iron. It is mounted on runners so as to be easily moved from place to place, and the lid is so hinged that it can be opened from either side. Through the middle runs a galvanized iron tank, filled with water. This is heated by means of exhaust steam from the drilling-engine, or any other convenient source. Full details of the construction are shown in the figures.

Principles of Agitation in Pachuca Tanks

By A. Grothe

In the Pachuca tank, agitation takes place in the body of the tank, during the downward motion of the pulp and does not manifest itself by any vigorous movement. The agitation in the air-lift is negligible on account of the shortness of the time during which it takes place, and its effect cannot be determined experimentally. The air-lift only serves as a convenient means of aerating the pulp, and lifting the solid particles from the bottom of the tank, after they have fallen through a column of solution equal to the height of the tank. This column itself has a downward motion, caused by the action of the lift. What concerns us is to know the rate of displacement of the solids in the solution.

Calling the velocity of the liquid v, and that of the solids v' we should endeavor to make $v' - v$ as large as possible. As v' is a function of gravity, and the retarding influence by the resistance of the medium, it is a constant in every case, determined by the degree of grinding and the consistence of the pulp. The factor v, however, is controllable within certain limits by regulating the quantity and pressure of the air. The greatest displacement of the solids in the pulp is obtained when the current in the lift is just sufficient to keep the cone clear of accumulation of solid particles. Therefore, the less vigorous the circulation the more perfect the agitation.

To determine the value of $v' - v$, a number of experiments were made. An experimental Pachuca tank of 18 in. diam. and 54 in. high, with air-lift, proportioned as in the large tanks, was fitted so that the air-lift discharge could be collected for a short time, instead of being returned to the tank. A charge consisting of a weighed quantity of ground ore and a measured quantity of water was made up, and when normal circulation was established, and sounding showed that no ore had settled near the bottom, samples of about 3 litres each were taken at intervals from the whole of the air-lift discharge, and investigated separately. As the results closely agreed, the average is used in the argument. Charges were made up of three different proportions of solid and liquid as follows:

I. 45.5 kg. ore with 136.5 litres water, giving 155 litres pulp of 3 to 1.

II. 64.41 kg. ore with 128.82 litres water, giving 155 litres pulp of 2 to 1.

III. 81.30 kg. ore with 121.95 litres water, giving 155 litres pulp of 1.5 to 1, from which the solids per litre of pulp were calculated.

(*a*) I, 294 gm.; II, 415 gm.; III, 524 gm.

The solids per litre of air-lift discharge were: (*b*) I, 426 gm.; II, 501 gm.; III, 580 gm.

The solids have therefore moved at a greater velocity than the water and $v' = \frac{(b)}{(a)} v$. The velocity of the solids was, therefore, I, 1.45 v; II, 1.21 v; III, 1.11 v.

The sizing test of the ore was as follows: All passed 80 mesh; 9.2% was retained on 100 mesh; 27.8 on 200 mesh; and 63% was finer than 200 mesh. A litre of pulp contained, therefore,

Mesh.	Gm.	Gm.	Gm.
(*c*) + 100	27.05	38.18	48.21
(*d*) + 200	81.73	115.37	145.67
(*e*) − 200	185.22	261.45	330.12

The air-lift discharge consisted of the following sizes:

Mesh.	Per cent.	Per cent.	Per cent.
+ 100	14.2	12.5	11.3
+ 200	39.4	32.4	30.3
− 200	46.4	55.1	57.4

and the solids contained in one litre of pulp:

Mesh.	Gm.	Gm.	Gm.
(*f*) + 100	60.49	62.63	65.54
(*g*) + 200	167.86	162.32	175.74
(*h*) − 200	197.66	276.05	338.72

The velocity of the particles of various sizes is,

$$\frac{(f)}{(c)} v,\ \frac{(g)}{(d)} v, \text{ and } \frac{(h)}{(e)} v, \text{ for the}$$

three classes, of pulp, therefore.

Mesh.	I.	II.	III.
+ 100	2.23 v	1.64 v	1.36 v
+ 200	2.05 v	1.40 v	1.20 v
− 200	1.07 v	1.06 v	1.03 v

The segregation of the particles takes place, not only according to size, but also according to specific gravity. To calculate the velocity of the sulphides, a sulphur determination was made before and during agitation, as follows:

Tank Charge

	I.	II.	III.
Percentage of solids	5.7	5.7	5.7
Grams per litre	16.76	23.65	29.87

Air-Lift Discharge

	I.	II.	III.
Percentage of solids	7.7	6.9	6.6
Grams per litre	32.80	34.57	38.28
Velocity of sulphides	1.95 v	1.45 v	1.28 v

The most interesting item of information obtained by these experiments is the displacement of the particles containing silver in the pulp.

Tank Charge

	I.	II.	III.
Grams silver per metric ton	995	995	995
Milligrams silver per litre pulp	292	413	521

Air-Lift Discharge

	I.	II.	III.
Grams silver per metric ton	1085	1046	1012
Milligrams silver per litre	446	526	587
Velocity of silver	1.53 v	1.27 v	1.12 v

So far we have only considered the relative velocity of the solids. To find the absolute displacement, it is necessary to know the velocity of the pulp in the air-lift. Experiments for the construction of empirical formulae are in progress. It is certain that those for lifts pumping water to a great height are not applicable.

Calling the velocity of the pulp in the lift V, then, the diameter of the lift being one-twelfth of that of the tank,

$$v = \frac{V}{143}$$

Taking V as 100 ft. per minute and the section of the lift as 1 sq. ft., then 100 cu. ft. of pulp is lifted per minute, which contains 88, 83, or 79 cu. ft. of solution according to the degree of density. Taking the last, as the least favorable, v is equal to $\frac{79}{143} = 0.55$ ft. or 6.6 in. per minute. The displacement of the particles in the solution is then:

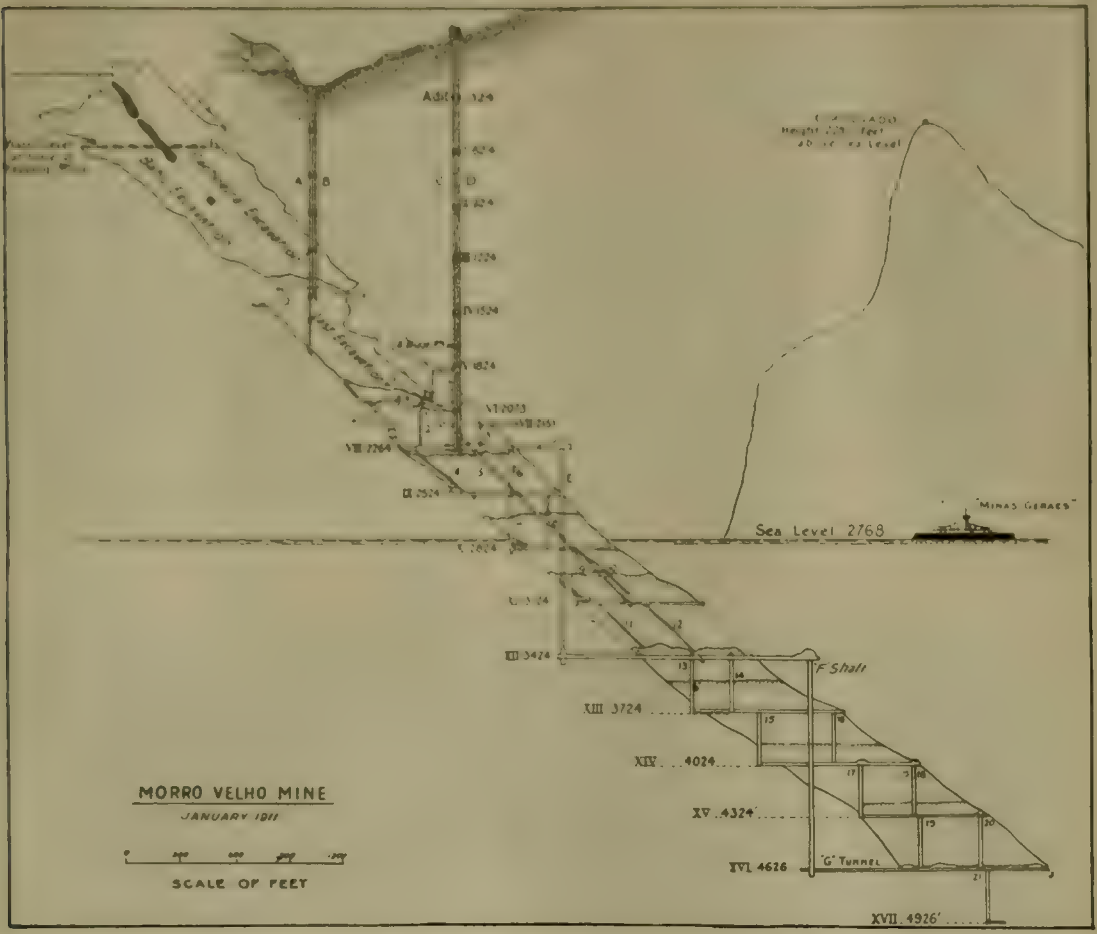
+ 100 mesh	0.36 v = 2.376 in.
+ 200 mesh	0.20 v = 1.320 in.
− 200 mesh	0.03 v = 0.198 in.
Sulphides in general	0.28 v = 1.848 in.
Particles containing silver	0.12 v = 0.792 in.

Apparently the displacement increases with v and the statement that for efficient agitation, v should be kept as low as possible, seems contradictory. But the experiments were made with the proper amount of circulation. If the latter is increased needlessly, the velocity of the liquid only will be increased and the values found above will become smaller.

The important facts brought out by this investigation, incomplete as it yet is, are: That all the components of the ground ore continually change their position with regard to each other and the solution, thus presenting the whole of their surface to be attacked by ever changing portions of the latter, leaving behind them a trail of quasi-saturated solution, which is obliterated in the air-lift (if not before) by secondary currents in the tank. The amount of this displacement, even in the most viscous of the pulps experimented with and for the finest and lightest of the particles, is several hundred times their diameter.—*Mexican Mining Journal.*

Morro Velho Mine

The Morro Velho gold mine in Minas Geraes, Brazil, has been worked continuously for 80 years by the St. John del Rey Mining Co., a London corporation. It is the deepest mine in the world. Level No. 17, which is now being developed is 4600 ft vertically below the adit or 4926 ft below the surface. A fuller description of the mine is given in the London letter of this issue.



Copper Production for Half Year

Hayden, Stone & Co., have prepared the table below showing the production for the first six months of 1911, in the estimated cost and the earnings per share for this year, on a 12½-cent metal basis, as compared with 1910.

	Production 6 months 1911	Estimated Production Year 1911	Production Year 1910	Estimated Cost 1911	Estimated Earnings per share 1911 (12½c. Copper)	Earnings per share 1910
Ahmeek	6,000,000	13,500,000	11,844,954	10c.	$6.70	$4.58

*When in full operation.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Battery Foundations

The Editor:

Sir—In your issue of July 1, 'Puzzled Engineer' makes some statements and asks some questions about battery foundations which would indicate that he is not following the progress of this part of stamp-mill construction very closely. The sketch entitled 'Form No. 1' was designed and installed by me in the Goldfield Consolidated mill in 1907, and has been fully described by J. W. Hutchinson in his articles on the Consolidated mill which have recently appeared in the *Mining and Scientific Press*.

The sketch 'Form No. 2' was also designed by me and has been installed at the Nevada Hills mill, which is expected to be in operation within the next sixty days. Both of these installations are the first of the kind that have ever been used, to the best of my knowledge. If 'Puzzled Engineer' wants information on these points, he should at least sign his name.

J. B. FLEMING.

Fairview, Nevada, July 5.

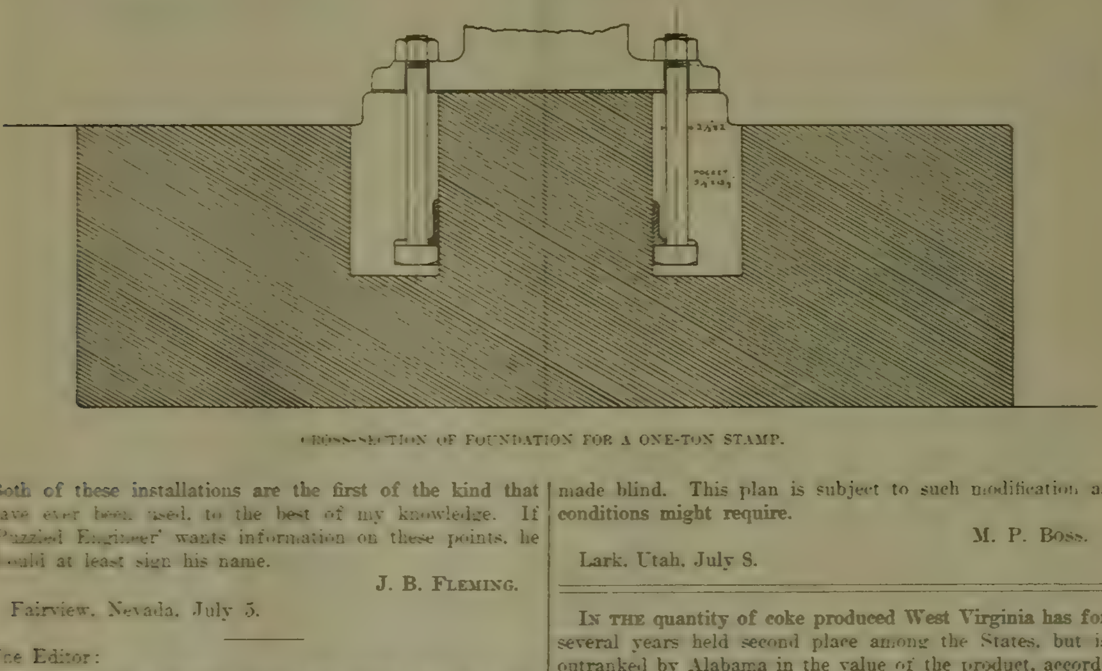
The Editor:

Sir—'Puzzled Engineer' raises the point of best form for battery foundations and shows three methods of anchorage, the adoption of any one of which need bring no serious regrets. But the three cuts he has shown are all of the same general form, built as though their prime object was to disseminate the effect of a tremendous blow from a central point to a broadened base some distance below. The pedestal idea for concrete battery foundations is all but universal.

Now the force of a single blow from a one-ton stamp, distributed through the bottom of a mortar having an area of [illegible] or two thousand square inches, would mean but slight pressure to each square inch, not counting the deadening effect of three tons, more or less, of mortar weight, and the cushioning effect of the ore. It is the [illegible] of blows producing vibration that we [illegible] foundations, and that is the one factor to consider. There is no particular objection to a pedestal form, if conditions will allow it, which is not generally the case in a stamp-mill, but a pedestal does not neutralize vibration as well as [illegible]. In other words, the closer to firm contact with Mother Earth the better, and a pit filled with concrete would be better than a pedestal.

The eight anchor-bolts commonly used for each mortar are an inheritance from wooden-block foundations. My personal observation leads me to believe that vibratory action on a tightly-tensioned anchor-bolt is so local that a bolt is as liable to break in a row of four bolts as it is in one or two (of the same size). Acting upon this idea, I years ago adopted the use of four 2½-in. anchor-bolts instead of eight of smaller size. While I am not prepared to say that no 2½-in. anchor-bolt ever broke, I have never known of such an occurrence, and it surely is so rare that it is not essential to provide for a rapid change.

I herewith show a plan of mine of a foundation for a one-ton (or less) stamp. The concrete is 9 by 3 ft. deep. The base of the mortar is 40 in. wide and the anchor-bolts are spaced 30 by 42 in. The anchor-bolts are 2½ in. by 2 ft., and are anchored by angles 5 by ⅝ in. by 6 ft. In this design the angles have a grip on the foundation, without weakness, far in excess of the bolt strength, but should any doubt exist, twisted steel can be suspended from the angles to reinforce to any desired extent. With the bolts in place the pockets can be filled with coarse sand, over which a crust of concrete can be laid and the pocket be made blind. This plan is subject to such modification as conditions might require.



CROSS-SECTION OF FOUNDATION FOR A ONE-TON STAMP.

M. P. BOSS.

Lark, Utah, July 8.

IN THE quantity of coke produced West Virginia has for several years held second place among the States, but is outranked by Alabama in the value of the product, according to Edward W. Parker, of the United States Geological Survey. The reason for this lies in the fact that the output of Alabama has in the iron-manufacturing centre of Birmingham and vicinity a local consumptive market, whereas practically all of the West Virginia coke is shipped to furnaces outside of the State. In reaching for these markets not only does the coke of West Virginia have to meet in competition the product of other States, but each district in the State becomes a rival with the other West Virginia districts and the result is exhibited in the statistics of production and value. Alabama ranks third in output of coke, her production in 1910 being smaller than that of West Virginia by more than 550,000 tons, but the value of Alabama's product exceeded that of West Virginia by over $1,800,000. The quantity of coke produced in West Virginia in 1910 was 3,803,881 short tons, valued at $7,355,233. Alabama's production was 3,249,027 short tons, valued at $9,165,821. In quality the West Virginia coke is better than that of Alabama, but the average price of Alabama coke in 1910 was $2.82 per ton and that of West Virginia coke was $1.93.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

AN EXCELLENT PAINT for iron, steel, stone, or wood is a mixture of soapstone and oil. On bridges, etc., it will last for years.

A SOLDERING MIXTURE that will not corrode like chloride of zinc, is made up of one pound lactic acid, one pound glycerine, and eight pounds water.

A RUST JOINT may be made by mixing 10 parts iron filings and 3 parts chloride of lime to a paste by means of water. Apply this to the joint and clamp up. It will be solid in 12 hours.

LINES omitted on a tracing can often be produced on the blue-print by scratching through the blue surface with a sharp pointed knife. If carefully done, the resulting line is much better than one made with erasing fluid.

SPRINGS are best tempered by using fish or bank oil. It gives sharper temper than black oil or cottonseed oil. When using fish oil, springs will stand up better if a shade less heat is used for tempering than when using black oil.

ALUMINUM POWDER is used to an increased extent in the manufacture of metallic paints and varnishes, its property of not tarnishing making it particularly suitable for this purpose. The paint is valuable in protecting iron and in rendering woodwork partly fireproof when applied in thick coats.

FROST-PROOF MORTAR may be made by taking one barrel of portland cement, one barrel slaked lime, and three barrels sharp sand. Mix the whole dry, then add sufficient carbonate of soda solution to make of proper consistence. The first setting should take place in one hour. After twelve hours good cement should have reached the final setting stage.

TO SOFTEN CAST IRON, heat the whole piece to a bright glow and gradually cool under a covering of fine coal dust, etc. Small objects are packed in quantities, in a crucible in a furnace or open fire, under materials which when heated to a glow give out carbon to the iron. They should be heated gradually, kept at a bright heat for an hour and allowed to cool slowly. The substances recommended to be added are cast-iron turnings, sodium carbonate, or raw sugar. If only raw sugar is used, the quantity should not be too small. By this process iron may be made so soft that it can almost be cut with a pocket-knife.

COKE is produced by two methods—in beehive ovens, where the coke is the only product recovered, and in by-product ovens, where all the important subsidiary products are conserved, such as gas, ammonia, creosote, and coal tar. At present the bulk of the coke made in the United States is manufactured in the old-fashioned beehive oven with an annual waste of millions of dollars worth of by-products. In 1910, according to E. W. Parker, 17.13% of the total coke output was made in by-product ovens, as against 15.91% so produced in 1909. The figures obtained by the Geological Survey show that there is a gradual increase in the use of by-product ovens. At the close of 1910 there were 2187 coke ovens in course of construction, and of these 920, or 42.07%, are by-product ovens.

ASBESTOS occurs in three type forms—cross fiber, slip fiber, and mass fiber—distinguished by the form of aggregation. The most valuable asbestos fiber occurs in cross-fiber veins. The fiber runs directly across the vein from side to side. Its length is thus limited by the width of the vein and ranges from [illegible] to 2 in. For the most part the veins of asbestos separate easily from the country rock, and, when broken across, expose the beautiful white fluffy asbestos fiber, with the sheen of silk. The highest grade of asbestos, about an inch in length, is common in the eastern provinces of Canada, but has not yet been produced in the United States. It is worth about $225 per ton. The lower grades, ranging from $100 down to less than $10 per ton, are much the more abundant in all asbestos fields. Slip fiber occurs along slipping planes or faults and shows the direction of the motion. Most of the slip-fiber asbestos is of low grade.

BITUMINOUS coal seams, when outcropping on the surface, can frequently be detected by the black color which they impart to the soil. When they outcrop on a hillside the black material will be carried down the slope by the combined action of frost and gravity, so that a narrow seam may give rise to a very wide black zone. In other cases a wide seam may be nearly completely covered with earth, and in the case of an easily oxidized coal, the outcrop may be marked only by some gray or red ash; therefore too much dependence should not be placed upon this indication. Samples of coal taken near the outcrop are almost valueless, as the coal will be oxidized, and as some coals oxidize more readily than others, little can be learned from such a sample as to the real character of the coal. Bituminous seams have been less disturbed than anthracite seams, hence are less likely to be seriously faulted.

GARNET is marketed chiefly in the Atlantic States, where it is used for manufacturing garnet sand-paper, and in the shoe industry for dressing leather. The value of the crushed and sized material is about $32.37 per 2000 lb. Freight from the Pacific Coast would not be much less than $15 per ton. This would leave about $17.37 per ton sacked at the mine here, out of which would have to be paid the cost of mining, crushing, washing, and sizing. While this looks as though it might leave a margin of profit, the fact that the total consumption last year was only about 2000 tons, and the main producers are in a position to increase their production almost indefinitely, means that in the face of competition they would simply reduce their prices. The consumption of garnet, instead of increasing, as might be expected, has actually decreased, owing to the production of artificial abrasives at Niagara Falls. If any large users were to establish themselves on the Pacific Coast, a deposit of garnet might become of commercial value, but at the present time it is not feasible to operate at a profit.

QUARTZ is used for a great variety of purposes, principally in the manufacture of wood filler, pottery, paints, and scouring soaps. In pottery quartz serves to diminish shrinkage in the body of the ware; it is used also in many glazes. Quartz for these purposes should be nearly free from iron-bearing minerals. Finely ground quartz is used in paints to increase the resistance of the paint to the weather. In scouring soaps and polishers ground crystalline quartz is preferred to silica sand, not only because of its greater angularity, but because of its superior whiteness. Massive quartz, crushed and graded to various degrees of fineness, is extensively used in the manufacture of sand paper and sand belts, and as a scouring agent with sand-blast apparatus. Much ground quartz is used in filters, and some of the most finely pulverized grades are used in tooth powders and in place of pumice as a cleaner by dentists. Crystalline quartz and sand have been used to some extent in the manufacture of silicon and of alloys of silicon with iron (ferrosilicon), copper, and other metals. Ferrosilicon is largely made in the electric furnace by using coke to reduce the quartz to the metallic state and some iron ore or scrap iron to alloy with the silicon. The resulting product, ferrosilicon, is used in the manufacture of silicon steel.

Special Correspondence

WASHINGTON, D. C.

Controller Bay Question.—La Follette Bill.—Provision for Development.—National Coal Reserve.—Investigation of Public Lands.

Washington is just now agitated over the question of who owns and controls the harbor of Controller bay, one of the two outlets for the rich Alaskan coalfields. Richard S. Ryan, claiming to represent the Controller Bay company, came to Washington and induced the authorities to exclude from the Chugach National Forest the land along the shore of Controller bay. Then he and his associates filed upon it. Now it is claimed that Ryan represents the Guggenheim syndicate, and that with their control of Cordova bay and the Copper River & Northwestern railroad, already built into the coalfields, this syndicate has a complete monopoly upon the transportation of coal from the Territory. Ryan, while here, insisted that he not only did not represent the Gugenheims, but that his company is a rival to that syndicate.

In spite of the urgent need of adequate and understandable legislation that will permit the opening of the Alaska coalfields, there is no likelihood of any action being taken at this special session of Congress. The Democrats made an iron-clad rule not to discuss any legislation except Canadian reciprocity and the wool schedule, and are living up to it. But the refusal of the Democrats to act has not deterred members of Congress from introducing bills which seek to regulate the disposal of minerals on the public domain. Robert La Follette, Senator from Wisconsin, the other day introduced a measure providing for a new leasing system. This first withdraws from entry and sale all public lands containing coal or other minerals mined for fuel, oil, gas, or asphalt in the United States. A citizen has the right to apply for a license to mine these minerals underlying areas not exceeding five sections and to use as much of the surface as shall be necessary for the proper conduct of the business. The bill further provides that the license shall not exceed 30 years, and a rental of not less than 10c. per acre shall be paid each year in advance, which may be abated by the amount paid in royalties each year. The bill provides that the licensee shall pay a royalty of not less than 8c. per ton 'mine run' on all coal or other minerals mined for fuel, and of not less than 60c. per ton upon mineral mined for hard asphalt, not less than 15c. per barrel of mineral mined for soft asphalt, not less than one-eighth of the value of the product of any oil well, not less than $50 per annum for each gas well not utilized, and at a rate of not less than 1c. per 1000 cu. ft. of gas when the product of such gas well is utilized.

James Wickersham, delegate from Alaska, has introduced an innocent-looking measure in the House which contains much more than its official title: "To establish a national coal reserve in Alaska and for other purposes." The bill provides that this national coal reserve shall contain 15,000 acres of land, 5000 acres in the Katalla or Bering River district, 5000 acres in the Matanuska coalfield, and 5000 acres in the Kenai peninsula. Section 2 of the bill provides that upon the reservation of the coal land as a national reserve for the use of the United States Government, all other coal lands in Alaska not included in the national reserve shall be open to entry and sale under the laws of the United States in force in Alaska. John E. Raker, representative from California, has introduced a resolution requesting the Committee on Public Lands to make a complete investigation of the administration of the public-land laws with reference to prospecting, locating, appropriating, and listing lands, especially of mineral lands. Mr. Raker wishes to know whether prospectors, miners, and mineral claimants have been denied, or unjustly interfered with in the enjoyment of rights and privileges guaranteed to them.

SALT LAKE, UTAH

Good Progress in Utah.—Increase of Production by Utah Copper.—Ohio Copper Doing Well.—Utah Mines Coalition.—New Ore-shoots at Tintic.—Pioche Merger.

The feeling in mining circles is more optimistic than it has been for a long time. From the different camps of Utah reports are coming of enlarged operations, attended by favorable results. There is nothing savoring of a boom, but mining men are finding less difficulty in financing their operations, several prospects are turning into mines, and established mines are hiring more men and reporting encouraging developments. The dividend record of the first six months for Utah mines shows an improvement over 1910. Without taking into consideration a number of close corporations and leasing companies which do not report, the mines of Utah paid out $5,371,142 in dividends during the first half of 1911. This is at the rate of $10,742,282 per year, as compared with $8,758,873 for 1910. Utah Copper leads with $2,310,256. If the price of copper rises as its friends predict, the Bingham mines should be able to make a still better record without increasing their production. Utah Copper's output is steadily creeping up. In April it went ahead of the corresponding month of 1910, being 8,169,248 lb., as compared with 7,902,643 lb. In May it was still larger—8,391,879 lb.—though it fell below May of last year, when the output was 8,862,913 lb. The Yampa property at Bingham is doing much better since the change in management. This has been accomplished through changed methods of mining and handling the ore, put in by Mr. Moodie, general manager. W. W. Bellows, president of the Utah-Bingham company, says that work will shortly be resumed on this property, which is controlled in London.

OHIO COPPER CO. MILL.

While the financiers are discussing what next to do with Ohio Copper, the mine management is going ahead and turning out copper at a rate which leads some enthusiastic people to predict that the mine may eventually do its own financing. Officials of the company claim that the cost is now only a trifle over 9½c. per pound, and that the property is earning at the rate of $250,000 per year. The mill is now handling 1700 tons per day, which amount will be doubled when the second unit is installed. In the Big Cottonwood district several properties are shipping, and work is being undertaken on numerous prospects. In Alta similar conditions prevail. It looks as though the Utah Mines Coalition Co. had a real mine, judging from the bodies of silver-lead ore already exposed, and the shipments which are steadily reaching the smelter.

In the Tintic district, the old reliables are shipping right along, while a great deal of new work is being undertaken. Among the significant developments recently have been discoveries in the Colorado and the Iron Blossom. In the former a new ore-shoot, paralleling the original, has been discovered, and in the latter a large ore-bearing cave has been broken into. These are taken to indicate the opening up of entirely new ore shoots in this end of the district. Sioux has paid [illegible] $30,000, making a total of [illegible].

Beaver county comes in with the report of some profitable results from the operations of the South Utah, [illegible] Cactus and Newhouse Mines & Smelters, and with the news that the Majestic company is accomplishing the unwatering of the Harrington-Hickory group and is opening up some good ore below the old water levels. The Moscow is shipping three to four cars of high-grade silver-lead ore per month, while the Sheep Rock is getting some streaks that run into the thousands of dollars per ton, with a larger quantity of lower-grade ore, for which a mill is being built. A syndicate backed by European capital is preparing to start a party from Salt Lake to explore the entire region which will be tapped by the Moffat road in its extension from its present terminus in Colorado to Salt Lake City. Many other prospecting parties are in this field and elsewhere. The closing in Salt Lake of a deal, after long negotiations which have been declared off more than once, for a consolidation of the Ohio Kentucky with the Nevada-Utah in Pioche, means a settling of the difficulties between these two companies and an extensive campaign of development.

BLACK HILLS, SOUTH DAKOTA

Work on Homestake Hydro-electric Plant.—Construction of Bismarck Mill.—Working Costs at Wasp No. 2.—Jungle Copper Mine.—Settlement of Columbia Litigation.

September 1 will see the work on the Homestake hydro-electric plant on the Spearfish practically completed. The lining of the $1\frac{1}{2}$ miles of tunnel with concrete is rapidly being finished, the machinery for the power-plant has been delivered, the intake dam is complete, and by the date mentioned it is expected that the plant will be ready to run. The operation of practically two-thirds of the Homestake's machinery by electricity will save enough boiler water to run nearly 100 stamps, and persistent rumors are afloat to the effect that the erection of a new stamp-mill is contemplated.

The Bismarck Consolidated Mines Co. put a crew of men at work on the first of July, and will increase the force and push work on mill construction in an endeavor to have the cyanide plant running by late fall. The property adjoins the Wasp No. 2, on Yellow creek, and has similar ore. The mill will have a capacity of 250 to 300 tons per day, but will be enlarged to 600 tons within a few months. The ore received in one-ton mine cars will be dumped into bins of 400 tons capacity, crushed to pass a $\frac{1}{2}$-in. ring in one No. 6 and two No. 3 Gates crushers, and further reduced to $\frac{1}{4}$-in. mesh in two sets of 16 by 36-in. Allis-Chalmers rolls. The plant will be driven by electricity throughout all departments. Zinc-shaving precipitation will be used. The general manager is Fred B. Hitchings, Deadwood. W. W. Graham is millwright in charge of construction.

Wasp No. 2 paid two dividends of 1c. per share each in June. The company is capitalized for 500,000 shares of $1 each. During May the mill handled 14,800 tons of ore from which bullion to the value of $29,249 was recovered. Total expenses, including general expense, were $15,040, or $1.0161 per ton. The June tonnage was 14,400, and bullion recovery practically the same as May. Since resuming sinking the North Homestake shaft, at Maitland, has been deepened 100 ft., and is 320 ft. deep. A small station will be cut at this level and sinking continued several hundred feet farther. Shipments of 6% copper ore commenced this month from the Jungle mine, in the Custer Peak district, to the Omaha smelter. The ore is an oxidized porphyry, although it shows a change at 65 ft., the lowest depth reached. There is a large body above this level which can be cheaply mined.

Litigation over the Columbia mine, at Keystone, has been settled and the interests consolidated under the incorporation of the Columbia Mining Co., capital stock 500,000 shares of a par value of $1 each. The officers are: John Marion, president; F. R. Griffith, vice-president; J. A. Bedard, secretary and treasurer. The directors are John Marion, John A. Marion, and F. R. Griffith, of Keystone; Thomas Gilroy and F. J. Marion, of Lead. A shaft 115 ft. following the dip of the vein showed a quartz body from 4 to 16 in. wide, worth from $40 to $150 per ton as shipped to smelters. Later a vertical shaft, planned for a permanent working shaft, was started, and at 12 ft. rich ore was encountered. The body at this point is 30 in. wide and is valued at $25 to $100 per ton. This shaft is 352 ft. distant from the incline shaft. The plans of the company for the immediate future include sinking the vertical shaft to a depth of 500 ft. and equipping the property with a modern mill to handle the ores by amalgamation and cyanidation.

LONDON

Poderosa Copper, Chile.—Prospects of Deep Working at the St. John del Rey Gold Mine, Brazil.

Many sharp words have been exchanged in connection with the management and development of the Poderosa copper mine in Chile. From the most recent information published, however, it is clear that Robert Hawxhurst, Jr., of San Francisco, the first manager, is being justified by events. The mine is in the Andes at Collahuasi, Chile, not far from the Bolivian border, and is situated 15,000 ft. above the sea. The ore deposits are rich in copper. The directors made the initial mistake of declaring large dividends without reckoning on the necessity for providing funds for further development, and consequently the company was soon in a critical position. The directors blamed Mr. Hawxhurst, who resigned, but later most of them had also to resign to make way for others. C. H. Macnutt was appointed manager in the meantime, and took control during 1909. The rest of that year and the first half of 1910 was occupied in reorganization, and by the middle of 1910 it was possible to increase the output. The total amount of ore raised during 1910 from the three different workings, Poderosa, San Carlos, and Rosario, was 28,530 tons, averaging 17.8% copper; 21,442 tons averaging 4%, and 5102 tons averaging 2.5%. The deliveries of first-class ore were 21,797 tons, averaging 22% copper and 7.8 oz. silver, shipped from Mejillones, and 1544 tons averaging 13% copper and 4.2 oz. silver, shipped from Antofagasta. Some of the ore delivered came from the dumps to the extent of 3400 tons, some of which averaged 25% copper. Development during the year exposed 17,180 tons averaging 23% copper, and on December 31 last the ore reserve was estimated at 35,000 tons averaging 22% copper and 7 oz. silver. The dumps are reported to contain 96,000 tons averaging 4.7%. In September Mr. Macnutt started to concentrate the dump ore by means of hand-jigs and sluice-boxes, and this work has already proved profitable. Owing to lack of funds, Mr. Macnutt has not been able to do as much prospecting work as is desirable, but now that the evil effects of premature distribution of dividends have been counteracted, he intends to conduct development work on a large scale in the near future. During 1910 the income from the sale of ore was £191,870, and the net profit was £38,471. The year began with a debit balance of £67,272, which is now reduced to £28,801. Since the close of the year the directors have been able to redeem £36,000 of debentures. Experiments have been actively conducted in connection with the concentration of second-grade and dump ores, and a plant is to be erected. It will be seen from the above record that Mr. Macnutt has done what Mr. Hawxhurst planned to do, and that the latter's estimate as to the capacity of the mine has been confirmed.

The Morro Velho gold mine in Minas Geraes, Brazil, is the deepest mine in the world. Level No. 17, which is now being developed, is 4600 ft. vertically below the adit, or 4932 ft. below the surface. The lode dips 45°, and operations below Level 8 are by means of underground vertical named 'E' and 'F', each 1200 ft. deep and extending from Levels 8 to 12, and 12 to 16, respectively. Level 16, at 4300 ft., has now been driven nearly far enough for the commencement of another shaft, 'G'. The levels are 300 ft. apart. As the lode shows every sign of persistence, George Chalmers, the manager, is making arrangements for work to be continued to a depth of 6500 ft. Efficient ventilation for the purpose of reducing the temperature of the air and rock is of course of prime importance. Before the 'F' shaft was completed the workings on the fourteenth and fifteenth levels were unpleasantly hot, but as soon as through connection was made conditions rapidly improved. At the present time the ventilation is effected by a Capell fan driven by an 80-hp. motor, at the surface, together with some auxiliary fans underground. It has now been decided to provide two more fans, only one of which will be put in commission at first, with a 150-hp. motor. As the depth of the workings increases the second will be started with a 300-hp. motor, and later the first fan will be driven by a 300-hp. motor. Close investigation has recently been made with a view to ascertaining the greatest depth to which the mine can be worked. During the four hottest months of the year, November to March, temperature readings were regularly taken of the air at each level and of the rock at the end of the 10-ft. holes. It was found that from adit to Level 8 the air temperature is slightly greater than that of the rock. Thereafter the rock temperature becomes greater. From Level 14 to 17 both advance more rapidly, a fact due to these levels having been open only a comparatively short time, and the rock having been exposed to the cooling effect of only a small quantity of air. The figures relating to the original temperatures when the rock was first exposed at various points and the subsequent fall in the temperature are of considerable value in helping to forecast future conditions. On Level 14 in 1906, when it had just been reached, the rock temperature was 98°F., and the air temperature 95°. As soon as the level was connected with the ventilating system the rock temperature fell to 92½°F., and that of the air to 87½. With the more efficient system of ventilation it may be assumed that the temperatures of air and rock will not increase so rapidly, but will advance in approximately arithmetic progression as in their course from adit to Level 8. The probable increase in air temperature may therefore be expected to be such as to bring the temperature at a depth of 6500 ft. to 95°F., which is practically the temperature of the workings at Level 16 at the time of writing, so it may be supposed that with efficient ventilation work can be carried on at this depth.

The present position at the St. John del Rey is admirably reflected in the eightieth annual report recently issued. The report covers the year ended February 28 and shows that mining, milling, and development work have given satisfactory results. The only adverse circumstance was the insufficient supply of water-power owing to drought, and the consequent extra expense on steam-power. The amount of ore raised was 193,195 tons, of which 189,600 tons was sent to the 130-stamp mill. The yield by amalgamation and cyanide was 98,726 oz., realizing £421,178, or 44s. 4d. per ton. The working cost was £265,058 or 28s. per ton, development £12,387 or 1s. 4d. per ton, and London expenses £3692. In addition £43,057 was allocated to capital expenditure; £5425 was paid as interest on debentures, £10,000 as dividend on preference shares, being 10%, and £50,078 was distributed on the ordinary shares, being at the rate of 1s. 10d. per share, an increase of 2d. per share as compared with the previous year. The reserve fund invested in high-class securities has been re-valued and now stands in the books at £96,472; it is used in part to improve the financing of drafts between England and Brazil. A new unit of water-power from the Peixe river will shortly be at work and will provide an additional 1000 hp. The ore reserve is estimated at 1,158,560 tons, or sufficient for five years' work. Owing to the nature of the methods of mining no further development will be possible for two years until the seventeenth or eighteenth levels are fully opened.

TORONTO, CANADA

Bush Fire at Porcupine.—Two New Camps Established.—Progress at Rea and Preston East Dome. — Discovery at Nipissing. — La Rose Dividend. — Danger at Crows Nest Pass.

The Porcupine branch of the Temiskaming & Northern Ontario railway is now open for traffic, though the ballasting of the last few miles has not been completed. The camp was visited by another bush fire on July 2, which destroyed the plant of the Dome Extension, the men employed escaping with difficulty. Captain Anchor and several of the force sustained severe burns in fighting the flames. The loss to the company is not serious, as the plant and building destroyed were of a temporary character. In fact, the stripping of a large area of vegetation by this and the previous fire, though resulting in some present inconvenience and loss to individual companies, is regarded as on the whole advantageous, as it considerably facilitates the work of the prospector in discovering surface exposures. The Bewick-Moreing syndicate has established two new camps: Camp No. 3 is situated on the lots adjoining the Dome Extension on the north and east, and Camp No. 4 on the Timmins group of claims in Deloro. A large force is engaged in stripping and tracing the leads.

The Porcupine Investors, Ltd., a new company organized in London, capitalized at $1,500,000, has acquired three claims to the north of the Dome and North Dome properties, and has let contracts for drilling to determine the depth of the orebodies. Development is being actively pushed at the Rea mines. The main shaft, now down 240 ft., will be sunk to the 500-ft. level and adits run to tap the big orebody in the main vein. A second shaft is being sunk, which will be connected with shaft No. 1 by an adit at the first level. Many new leads have been found by surface prospecting. At the Preston East Dome a new vein 15 ft. wide has been discovered on a property adjoining the Dome, which will be opened up immediately, power being supplied by a 24-hp. boiler. A good find has been made at the Foley-O'Brien in driving at the 160-ft. level. The vein is quartz, assaying $10 per ton, intersected with rich stringers showing free gold. On a claim of the Armstrong-Booth syndicate, south of the Rea, a number of stringers have been found from which free gold has been panned out in large amounts. The Achilles, a Montreal company, capitalized at $1,000,000, operating to the north of Porcupine lake, has found visible gold at the 125-ft. level in a quartz vein 7 ft. wide. The Vipond has cut No. 3 vein at the 100-ft. level where it shows free gold.

A new vein of high-grade ore has been found in a crosscut at the 100-ft. level from the No. 123 shaft of the Nipissing. It is near the O'Brien boundary and is the first tangible result of development in the Keewatin formation in this part of the property. Good ore is also being taken from No. 12 shaft, which has been pumped out. The annual report of the Buffalo mill shows a recovery of 86.90% of all silver mined, 41,484 tons, of an average mineral value of 36.07 oz. being treated, making a total of 1,496,255 oz. handled. The La Rose continues its policy of accumulating a large cash surplus instead of paying heavy dividends. Its total income for the first five months of the year was $809,028, the expenses amounting to $273,895, leaving a profit of $535,132. Its present cash surplus applicable to dividends amounts to $1,300,000. The Trethewey has increased its capital from $1,000,000 to $2,000,000. A new orebody cut on the 150-ft. level of the Nova Scotia, where the shoot is 40 ft. long by 4 ft. wide, of good milling ore, is yielding well. As the vein has been found on the surface, the ore is supposed to carry to the upper levels. The Wettlaufer, in the South Lorrain area, is installing a 10-stamp mill.

A report by R. W. Brock, Director of the Canadian Geological Survey, has excited grave apprehension for the safety of the mining town of Frank, Alta. Mining operations have so weakened the northwest shoulder of Turtle mountain, which overhangs the town, that a landslide similar to that which occurred in 1903 is threatened. The mountain has been under inspection by the Geological Survey since that catastrophe, and last year two small cracks were detected which have since become more pronounced. The mine is operated by the Crows Nest Pass Coal Co. The report conveys an urgent warning that any further undermining may result in disaster.

FAIRBANKS, ALASKA

New Company.—Core Drilling.—Theft at Chena Mill.—Five-Stamp Mill for Bedrock Creek.—Good Ore on Wolf Creek.—Placer Gold.

Following the mill-run of 66 tons from the Golden Sherrard lease, which averaged $71 per ton, the lessees, who also hold an option on the property, have incorporated for $120,000. The Newsboy and Lucky Lad claims will be held by the Newsboy Mining Co., enough stock being sold to take up the option of $20,000, and to erect a hoist and mill. For development purposes, $100,000 worth of stock was set aside, and was all subscribed locally in twelve hours. A 5-stamp mill has been ordered by wire, and will be ready by the middle of September.

The Fairbanks Core Drill & Mining Co. has ordered a core-drill to be shipped from Seattle by June 1; stock in the company has been selling steadily, only about 1000 shares being left from the block set aside for operating expense this season. E. H. Mack, secretary and manager, has already made tentative contracts for drilling holes on promising properties for an interest in the ground. Goyette & Jacobson have sold their Fairbanks creek properties to McGinn, Berry & McIlroy. The last mill-run from this property returned $74 per ton, and the bottom of the shaft shows a strong vein. A contract will be let for sinking the shaft another 100 ft. During the last month, Alois Frederick has timbered 100 ft. of the lower shaft on his Vault creek property and installed a boiler and hoist. Plans are being made by McDonald, Drury, Cathcart, and Friedrich to further prospect the extension of the Friedrich's vein, bought from Hoel Bros. & Co. An explanation for the slender returns from the early runs at the Chena customs mill has been found. A former employee of the mill has been arrested and charged with stealing amalgam. Of five or six of the early runs which were made at the Fairbanks mill, it was noticed that the amalgam on retorting shrank 75 to 99%, where the normal shrinkage should have been not over 50 per cent.

Walter Hall, of the firm of Rhoads & Hall, of the Gold Coin claim, on Bedrock creek, has already shipped a 5-stamp Joshua Hendy mill, from San Francisco, for use on the claim. The mill has already been paid for by ore taken out in development work. A recent run of 54 tons at the Chena mill netted $6700, while a 90-ton lot just being milled is expected to net between $15,000 and $20,000. A quarter of a million dollars' worth of ore is already blocked out, and the normal output of the mill should not be less than $1000 per day. The battery is fitted with front chuck-block and back splash-plate, this arrangement being found very satisfactory for the free-milling ore on that claim. A vein which has attracted much attention because of good mill-runs and high assays of samples, is owned by M. Grummere, on Eva creek, a tributary of Ester. A half interest was recently acquired by Jim Lennon and 'Shorty' Thomas. The vein is 8 ft. wide and assays of samples taken from the pay-shoot run from $50 to $100 per ton. The Herschberger vein, owned by Zimmerman and Herschberger, has recently been acquired by Gordon & Sterling. This was located last winter and is 5 or 6 ft. between walls, 2 ft. of which is comparatively high-grade ore. The whole vein will pay to mill; there is now a large shipment awaiting treatment at the Chena mill.

A small lot of the ore found on the Wolf creek properties belonging to Balzimer & Nordale was put through the Fairbanks mill. This gave returns of over $100 per ton, the concentrate assaying a trifle less than $1000 per ton. The main cross-cut is still being driven to cut other veins, as there have been five veins discovered on the surface, that should be cut in another 600 ft. Steady development on the adjoining property, owned by Horton & Solomon, shows the vein to have three bandings, a 6-in. high-grade streak in the hanging wall, a 2-ft. filling in the centre of rock that will mill close to $40, and 3½ ft. in the foot wall of lower grade that will pay to mill. The Fairbanks Quartz Development Co. has awarded the contract of sinking a 200-ft. shaft to Gus Peterson. The plant is being moved to the ground and work will commence immediately. The Bonding & Leasing Co., of which F. S. Gordon is the moving spirit, is an assured fact, as the $10,000 guarantee was easily raised, and W. B. Vanderlip is already on his way in to take charge of the practical work of the company. Much placer gold is being brought into town and sold to local banks, although the Wells Fargo Express Co. has diverted some to San Francisco. The season's output will be very satisfactory, judging from the present outlook.

NEW YORK

State of the Copper Market.—Production for June.—United Verde Dividend.—Superior & Boston.—Interest in Pioche.—Little Interest in Porcupine.

The intense heat prevailing made the celebration of the national holiday a welcome interruption to market activities, or perhaps 'inactivities' would be a better word. In copper there has been a marked effort to magnify a little active buying into a demand that would immediately so diminish existing surplus as to make a 'runaway market' a real danger. Daniel Guggenheim gravely commented upon this phase of the copper situation in a recent interview. Much has been made of the splendid existing foreign demand which has been for some months reaching high-record figures. Conservative judgment would apparently look for a slight reaction rather than further increase in this direction. Mr. Guggenheim's views and Henry Krumb's recent estimate of Utah Copper are hardly harmonious. Mr. Krumb says that Utah Copper can for the next fifteen years produce 150,000,000 lb. of copper annually and lay the product down in New York at a cost of not more than 7½ cents per pound. When it is considered that Utah will soon be milling 20,000 tons of ore daily, or more than 7,000,000 tons annually, a 'runaway copper market' seems an imaginary danger. The tonnage to be handled by the Utah mills will equal the total tonnage of all the Lake mines and twice that of the whole camp of Butte. A possible shrinkage of 10,000,000 lb. is expected in the Producers' report, but the metal market is dull, with 12¾ quoted, and sales are made at fractionally less. Operators are evidently hoping for improved metal prices, and curtailment is about as much in evidence as at any time during the past nine months. Anaconda smelters turned out 21,850,000 lb. in June, against 23,254,-

UNITED VERDE SMELTER.

000 lb. a year ago, and 23,595,000 lb. in June 1909. The Phelps-Dodge output for June was 10,893,714 lb., as against 11,253,309 lb. in May, 11,063,454 lb. in April, and 12,236,-689 lb. in June 1910. In the case of the Calumet & Arizona, the Shannon, and other producers, there is apparently about the same proportionate shrinkage. There is good ground for the opinion that this action is a sane conservation of ore reserves by prudent management, rather than any concerted movement toward curtailment.

W. A. Clark, former senator from Montana, in his capacity as stockholder of the United Verde, had a bad shock when he met with the company's board of directors and decided not to declare the usual monthly dividend of 75 cents. The Clark mines have never lent their support to the policy of curtailment, but in this instance there have been some recent severe cave-ins, doing further damage to smelter foundations, and necessarily curtailing output. The real question is whether Mr. Clark can justify his action as director, with himself as shareholder. Greene-Cananea is apparently beginning to come into its own. May costs were brought down to 9c., and earnings were at the rate of $2,000,000 per year, which would be equivalent to 80c. per share upon the 2,500,000 shares outstanding, and equal to 13⅓% upon the present market price of the shares.

The shareholders of the Superior & Boston are to hold a special meeting at Boston, July 25, to authorize an increase in the capital stock of the company of 50,000 shares. The company's treasury has been reinforced by a loan of $200,000 secured through Hayden, Stone & Co. As an example of the force of sentiment in making markets, the course of Lake Copper deserves consideration. Some fifteen months ago the shares were selling around $94 per share on possibilities. Now the possibilities are being realized. Exploration work has reached the eighth level and there have been no disappointments so far. Notwithstanding this, the shares are selling for some $50 less than the high quotation record, while intrinsically worth more now than ever at any time heretofore. South Lorrain is possibly to develop into a real rival of Cobalt. Good ore has just been found on the Belle Ellen, which lies about a mile north of Wettlaufer; some of the ore is as high as 6000 oz. of silver per ton.

The merger story concerning the properties at Pioche has been revamped and is being passed out once more. The news is important in the Eastern market on account of the Nevada Utah stockholders, who are many, and who all have staggering losses, and who would all welcome any news that would galvanize some life into this issue. If the Nevada Utah, the Ohio Kentucky, and the Pioche Consolidated can finally combine on some real operating basis, the consolidation will have an interested public ready made and waiting for market movements. The Nevada Superior Mines Co., composed of people in and about Rockford, Illinois, and operating at Humboldt, Nevada, is about to build a 75-ton mill and concentrator. The Porcupine boom seems dead. It was many times repeated that the long-looked-for activity would appear the moment the railroad opened for passenger traffic. This occurred two weeks ago, but there was not even a ripple of response in the market. Forest fires now appear to furnish the only exciting news.

BUTTE, MONTANA

SMELTER PRODUCTION FOR JUNE.—LARGE SCALE OF WORK OF THE ANACONDA.—SALE OF ALICE G. & S. M. CO.—CHINESE INSPECTOR OF MINES.—REPORT OF TUOLUMNE C. M. COMPANY.

The official figures of the Washoe and Great Falls smelters for June show that the production was 21,850,000 lb., as compared with 21,700,000 lb. in May. The increase of 150,000 lb. was largely due to the Tuolumne shipping more ore than in May, which made the production of that company in the vicinity of 600,000 lb. as compared with 500,000 lb. in May, while the North Butte also ran a little over the average of 2,000,000 lb. for many months past. Of the production of 21,850,000 lb. the Washoe smelter at Anaconda turned out 16,700,000 lb. of copper and the Great Falls smelter 5,150,000 lb. All the ore of the North Butte and the Tuolumne companies goes to the Washoe smelter. The mines of the Anaconda company had practically the same production as in May. The East Butte company produced about 1,100,000 lb., so that the total production of this district for June was 22,950,000 tons.

Some idea of the immense amount of work carried on by the Anaconda Copper Mining Co. and the amount of money required each month to pay the employees may be gained from the fact that, at the present time, there are over 12,000 men on the payroll in the various departments of the company's works; nearly 6000 in Butte alone. When it is considered that a curtailment in the copper production of 15% is in force, and that other departments of the company such as the lumber, coal, and smelters must necessarily also curtail work, the number of men employed is surprisingly large. The miners are paid $3.50 per day, but there are at least 2000 who receive considerably over that amount, and it is a conservative estimate to say that the men altogether will average $3.75 per day, so the money required is nearly one and a half millions per month.

The fight in opposition to the sale of the Alice Gold & Silver Mining Co.'s property to the Anaconda company is to come up on July 12, which is the time set for the hearing of the application of the Anaconda company for the dissolution of the Alice company. A large number of the stockholders residing in New York, Boston, Salt Lake, and Butte have filed objections to the sale, and a fierce legal battle is expected. It is claimed that under the laws of Utah, where the company is incorporated, every stockholder must give his assent before a sale of the property can be legally made. It is stated that it is an old Utah law that a corporation cannot dispose of its property without the consent of every holder of stock. It may be remarked that quite a large number of the New York, Boston, and Butte stockholders who are contesting this sale are holders of Butte Coalition stock, and that some of the same grounds under which the protest is being made will be later brought forward to prevent a dissolution of the Butte Coalition company. A prominent New York lawyer has been engaged by the minority stockholders to conduct the case in their behalf, and it is understood that he will be assisted by at least two others who are prominent in corporation and mining law.

E. H. T. Chen, the supervisor of mining and smelting for the Chinese Government, has completed an examination of the methods of handling and treating ore at the Washoe smelter, and has gone to Tooele to inspect the plant of the International Smelting & Refining Co. He proposes to visit every mining centre in this country before returning to his native land.

The net profit of the Tuolumne Copper Mining Co. for the year, as shown by a statement filed with the Assessor for taxation purposes, was $24,768, as compared with $112,619, according to the statement filed the previous year. The gross revenue for the present year was $480,950, and the total amount of ore extracted was 31,509 tons. In connection with this year's report, it may be pointed out that the company paid two dividends, in February and May, which it did not do last year, and, in addition, has gone to an immense outlay in the past few months in installing new equipment. The annual meeting of the company was held a few days ago, and the reports submitted by the president and secretary-treasurer were deemed of a most satisfactory nature. The report, however, only deals with the affairs of the company for seven months, from June to December, at the end of which month it had a cash balance of $323,839. The by-laws of the company have been changed, and henceforth the annual meetings will be held in March instead of June, and the reports will be for the twelve months. From June 1, 1910, to December 31, the company shipped 18,957 tons of ore, containing 3,112,288 lb. of copper averaging 8.199%, and 58,965.56 oz. silver. The gross value of the metals was $293,738, and the net value, after deducting smelter and freight charges, was $177,885.

General Mining News

ALASKA

Valdez District

At the W[illegible] tunnel [illegible], on Mineral creek, near Valdez, the adit is being driven by three shifts at the rate of 4 ft daily. The vein is reached by a crosscut, and drifting on the vein is in progress. The ore is said to be high grade in gold.

Two quartz claims have been located in the Sheep Bay district by R. F. M[illegible]ard, J. M. Lathrop, and Thomas Blainey. One, known as the Mabeso, is situated three quarters of a mile west of Sheep bay and 1500 ft south of the glacier; the other is called Crossroad and is one mile west of the bay and 2000 ft south of the glacier. The King and Queen claims have been located by L. C. Townsend and Jess Crawford. One is near the Sunnyside and the other near the Wild Rose.

A great many quartz locations have been made in the vicinity of Valdez and the outlook for developing an important mining district there is promising. Some rich ore has been found in Cordova district, and numerous claims located. The veins are from 1 to 2 ft. wide, and are rich. Snow has, until recently, greatly retarded a more vigorous development of these prospects. It is said the town of Valdez is almost deserted, nearly all of the able-bodied men having gone out into the hills to prospect for gold-bearing quartz. The discoveries of last fall were made so late in the season that it was impossible to get in supplies, owing to the snow. This summer season will see the necessary winter supplies on hand, in most cases, to continue work throughout next winter.

The Alaska Gold Hill Mining Co. has established a camp at its mines near Bigelow on Mineral creek. A crew of men has improved the trail up the glacier to the Valdez and Ibex properties, avoiding the larger crevasses, filling in the smaller ones, and draining off the water; the men are placing the trail in excellent condition for packing supplies. A large crew is at work on the Ibex, crosscutting the lead at a depth of 250 ft. The tunnel is in 100 ft. The vein on the surface is from 1 to 3 ft. wide. The work is under the supervision of Sam Conninger, formerly of the Ellamar mine.

MAP OF ALASKA.

These are reported to be [illegible] producing well [illegible] Katalla oilfield and [illegible] other outfits are about ready to commence operations. A pipeline has been laid from what is known as the old English property, to storage tanks holding 15,000 gal. A small refinery has been built at Katalla and the gasoline made there is all sold to local consumers.

ARIZONA

Cochise County

John Pearce is said to have made a good find at the famous Commonwealth mine at Pearce. The Shattuck-Arizona Copper Co. has suspended operations at its mine, due, it is said, to the low price of copper. One hundred and fifty men are thrown out of employment.

The annual report of the Calumet & Arizona, just issued, shows a production in 1910 amounting to 28,020,506 lb of refined copper, with gold and silver content of $265,364. The net profits were $1,142,716, of which $800,000 was disbursed as dividends. The company now has assets, exclusive of mines and surface works, of $3,706,774, of which about half is cash.

Gila County

It is reported that the Sleeping Beauty Copper Co., which owns large holdings in the Sleeping Beauty mountains, nine miles northwest of Globe, will start work at once sinking a double-compartment shaft. At the Miami concentrator, at Globe, three units have been in operation during the past month, turning out about 65 tons daily of 40% concentrate, with net extraction of about 75% of the sampled value of the ore treated. This percentage is expected to be materially bettered with long operation of the plant.

Graham County

The work of more fully equipping the property of the Frisco Placer Mining Co., on the San Francisco river, seven miles below Clifton, is now in progress. It has been decided to use water for the whole process instead of only the latter part as originally planned. A cableway is being constructed, and to this cable will be attached a plow for loosening the material, to be followed by a number of scrapers, also attached to the cable, which will pass over 3-in. grizzlies. Oversize will be wasted and the undersize fed to trommel. The oversize from first trommel will go by belt-conveyor to waste dumps; undersize will go to a second trommel, screening 16 mesh; undersize from here to two fine sluice-boxes, oversize to coarse sluice-box; overflow from fine sluices through a Pierce amalgamator. The full plant operating will necessitate 12 men, and will use about 500 gallons of water per minute. A gasoline engine furnishes motive power.

Maricopa County

J. S. Baycroft is authority for the statement that work on a large scale will be started on the Palo Verde mine in the Saddle mountain district. There are four drifts on the property, 112, 110, 45, and 35 ft. deep, respectively. Drifts 125 ft. in length and 12 test-pits have proved an orebody 2100 ft. long and 600 ft. wide which assays $3.50 gold, $1 silver, and 2½% copper. The Buckeye railroad is only 18 miles from the property.

Mohave County

The Tom Reed Gold Mines Co. lately paid another dividend, disbursing about $40,000 in a 4% dividend. This is the largest disbursement since the company was incorporated and shows the big earning capacity of the mine. The ore that is being opened on the 550-ft. level indicates that the property will become one of the largest dividend-payers in the territory. S. C. Bagg has made arrangements for the sale of the Cyclopic mines, in the Gold Basin district, to an Eastern corporation represented by George Crearar and B. L. Smith. During the ten years just past, while the property was under the management of Mr. Bagg, the ore reserves have been largely increased. The milling plant will be remodeled.

Pima County

The Golden Age company is developing its property in the Comababi district, 64 miles west of Tucson, and plans to build a mill. J. M. Shrote is optimistic regarding the future of that neighborhood and says that the entire district is worth prospecting.

Pinal County

The Sterling Development Co. has started drilling for oil on its property near Mammoth. It is in this neighborhood that an 800-ft. well was sunk by Sullivan and associates and abandoned because of conflicts among those interested.

Yavapai County

The actual work of sinking the main shaft on the property of the Arkansas & Arizona Copper Co. has started.

CALIFORNIA

Amador County

The new 500-hp. hoist for the Argonaut mine is now being installed. The interior of the old hoist-house has been rearranged and the auxiliary equipment has been in place for some time. The Argonaut is 3800 ft. deep. Work was started last week in unwatering the shaft of the Mitchell mine preparatory to resuming operations. The mine has been idle for some months. It is the hope of those in the vicinity that the affairs of the company have been arranged so that this property may be worked in a manner that will give the mine a fair test as to its value. It is reported at Jackson that the South Eureka Mining Co. has purchased the Oneida mine, near Sutter creek. This property adjoins the South Eureka on the south, and has a good productive record.

Butte County

Another big dredge for the Natomas Consolidated was floated last week two miles south of Thermalito. The buckets are of 13 cu. ft. capacity and dig 35 ft. below the water-line. The entire boat contains 675,000 ft. of lumber.

Calaveras County

The Fox mine, near San Andreas, operating by the dredging process, was closed down last week by an injunction issued by the United States Circuit Court for obstructing the navigability of the San Joaquin river.

Eldorado County

Remarkably low costs are reported from the Sunrise mine, in the Kelsey district, about 6 miles north of Placerville. The mine is equipped with a 10-stamp mill and is worked by an open-cut. The breast, which extends from the hanging to the foot-wall, shows a 15-ft. face 40 ft. high. Two miners, working one shift of eight hours, with one mucker or car-man, supply ore enough to keep the 10 stamps running continuously, 40 tons being reduced by the mill every 24 hours. The actual cost of mining and milling ore at the Sunrise is between 62 and 63 cents per ton.

Mariposa County

A vein of rich ore has been uncovered at the 300-ft. level of the Bondurant mine at Coulterville. Ten men are at work sacking the ore. It is said that the 10-stamp mill is to be started soon. George H. Gerkin is superintendent. The Louisiana mine, adjoining the Bondurant, has been bonded to G. F. Dyer, consulting engineer of the Merced Development Co., of Merced.

Placer County

(Special Correspondence.)—A large building is in course of construction at the Rawhide mine, near Towles, to be used as a boarding house and for company office. The gravity tramway is nearly completed, and plans for a new mill are under consideration. A large amount of ore is available in the mine which now only needs a suitable mill for its reduction. The development consists of three adits in each of which large ore reserves are exposed. A rich find is reported having been made in the Home Ticket drift mine near Last Chance, east of Forest Hill.

Towles, July 9.

Tuolumne County.

(Special Correspondence.)—The water is being taken from the shaft of the Mazeppa mine, a mile south of Stent, with a view to further development. Some very good ore has recently been discovered near the south end of the vein. The management of the Golden Rule Mines Co. is contemplating unwatering the lower levels of that property to further develop the large bodies of low-grade ore on the 1400-ft. level and below it. The shaft is down 1400 ft. and a winze is down 400 ft. below that level.

Stent, July 8.

COLORADO

Chaffee County

Clyde Manamaker and Casey Gibbs have located 15 claims near Salida on which there is a vein of 1½ to 2% lithium ore. The property is within one mile of a railroad and can be mined and loaded on the cars very cheaply.

Gilpin County

The Black Jack mine in Silver gulch is to resume operations, a new company having been organized under the name of the Black Jack Mining Company to work the property, which is situated within a few hundred feet of the Coaley mine. The surface improvements consist of a good shaft-house which encloses a 25-hp. boiler and hoist. The main working shaft is down a depth of 140 ft., and it is the intention of the new company to sink it 100 ft. as soon as the necessary repairs are completed on the surface.

Hinsdale County

An option on the Highland Chief properties has been granted to a syndicate represented by C. H. Martin, following an examination and report by Edwin Chase of Denver. Arrangements have been made for systematic development and production. Additional equipment, including a tube-mill of 100 tons capacity, will be purchased for the new Rankin process plant, it is reported, and it will be opened for custom ore. The test runs on the refractory ore from Black Crook made in the Rankin plant are said to have been entirely satisfactory.

Lake County

W. H. Covey and associates have secured a lease on the Fairplay and adjoining property to the north and west of Adelaide Park. An electric hoist is to be put in and active prospecting started at once.

Ouray County

The White Cloud, near the Guston in the Red Mountain district, is unwatering its shaft preparatory to active development work. Thomas Darby, of Denver, is in charge.

Park County

A new find in the famous old Tarryall placer district has revived interest in Park county. Look Bros. have found gold nuggets in the bed of Deadwood creek, which is a tributary of the Tarryall, and although the property is only 3½ acres, the owners are said to have refused an offer of $50,000.

San Juan County

A rich find has been made by Judson Clevenger on his group of claims on Sheep mountain in the South Mineral Creek district. A 3-ft. vein of ore which assays 2.44 oz. gold and 231 oz. silver has been cut at about 400 ft. from the portal of the main working adit. Officials of the American Smelting & Refining Co. have been spending considerable time at the Silver Lake mine. It is reported that a shortage of lead ore at the Durango smelter has necessitated the operation of the Silver Lake mine by the smelting company and that it will resume operations in a moderate way at once.

San Miguel County

The Nelson mill has resumed operations, and [illegible] are dropping on ore from the Nelson vein, which is under lease to George Hart and I. E. Brown.

Teller County

Work of [illegible] the West Home mill at Cripple Creek is progressing at a good pace under the supervision of Ed. Holmes of the United Gold Mines Co. and John [illegible] McMahon, the Cripple Creek consulting engineer. It may be [illegible] before the treatment of ore can commence. There are many changes to be made, involving an expenditure of several thousand dollars.

IDAHO

Idaho County

S. R. Gayton, general manager for the Idaho Realty, Power & Mines Co., has arrived at Dixie and states that within a few weeks work will start on the erection of a power plant and opening of the placer holdings on Crooked creek.

Shoshone County

Following the recent exposure of a good vein of galena in the Blue Star mine, near Kellogg, the officers of that company have decided to increase their working force in the mine and push development work as fast as possible in the hope of putting the property in the producers' list by next season. The Bullion Mining Co. has a force of 20 men working on the wagon road from Borax to the mine, also repairing the compressor and rebuilding the bunk house which was destroyed by the forest fires of last August. As soon as the road is completed and the buildings erected, sacking will be resumed. With a new wagon road to the railroad, the Bullion will soon be ready to make a shipment of copper ore to the smelter. The Dalmatia Mining Co. has started a new adit on its property on Pine creek. Ed. Hedin, of Wallace, has been elected secretary. The directors of the Success Mining Co. have declared a dividend of $15,000, being the second one of that amount paid by the company. The Surprise Mining Co. is giving its remodeled mill a trial run. The mine is on Pine creek, four miles south of Wardner.

MONTANA

Silverbow County

(Special Correspondence.)—It would appear that the curtailment agreement existing among the leading copper producers of the country is to be continued after its expiration on August 1 until such time as the increased demand for the red metal relieves a large part of the present existing surplus. Such a conclusion is reached from an interview given by John D. Ryan, president of the Amalgamated Copper Co. He said, in speaking of the copper industry: "The surplus accumulation after the panic of 1907 is being gradually worked off, and with a return of good business conditions I look for better times for the copper industry, with considerable increase in the prices for the metal." Then he added: "In the meantime I don't think we are likely to produce any more copper than at present." Mr. Ryan, in reply to a question as to the correctness of the published statement that the Amalgamated Copper Co. had taken over the Missouri River Power Co., said that the published statements were incorrect. He added that the Amalgamated company had not acquired and did not intend to acquire control of any other power company. He said that the company did not have any interest in the Missouri river company and has not for years.

When the new furnace is installed at the East Butte smelter it is estimated that the company will be in a position to produce 2,000,000 pounds of copper per month. This new furnace will make the third, and will be finished in the course of the next three months and possibly sooner, as all the material is now on the ground. While it is not the intention of the company to run the smelter to its full capacity under present copper market conditions, there will possibly be some slight increase, as the company has a large amount of ore [illegible]. When the improvements now being made [illegible] the company expects to be in a position to resume [illegible] immediately.

Some time ago the North Butte company purchased the Berlin company's claim, and as the stockholders of the Berlin were without property, application was recently made to the court for permission to dissolve. The order has been made, and John D. Pope, manager for the North Butte company, W. D. Thornton, stockholder of the Berlin company and also president of the Greene Cananea company, and Harry Holp, also a stockholder of the Berlin company, named to act as trustees in the dissolution proceedings. The Berlin claim is now one of the North Butte's most valuable assets. The Tuolumne company has declared the regular dividend of 15c., payable on August 15. "We can very easily take care of this rate of dividend and meet all obligations without impairing the treasury to any extent," said Mr. Hickey, the president, recently, "but with the market conditions as they are at present, it would be folly to attempt to increase the rate, as some think we would be justified in doing. The market looks good for an improvement, and it would not surprise me to see the surplus largely wiped out, and 13c. copper in the next few months; but we will have to wait until that time arrives before we increase the dividend. We are increasing our ore reserves every day and shipping about 200 tons per day, and when the new equipment is in place we will be in a position to ship at least 500 tons per day to the Washoe smelter." Some parts of the new surface plant have already arrived, but it is not believed that the equipment will be in position and ready to be operated much before the middle or latter part of August. It will be all installed without a delay of more than three days in mining operations.

GREAT FALLS SMELTER.

Butte, July 7.

NEVADA

Churchill County

The test run of one month has been completed at the mill of the Nevada Wonder Mining Co., at Wonder. It consists of a 10-stamp battery (the stamps weighing 1400 lb.), classifiers, tube-mills, concentrating-tables, Chilean mill, and cyanide plant. The capacity is 100 tons per day. It was built by the Mill & Smelter Engineering Co., of New York.

[illegible] County

[illegible] Wheatley and Roscoe [illegible], working on the [illegible] Nevada [illegible] of the Bamberger-Wheatley property, at [illegible], have opened up a vein of [illegible] which they are [illegible] from the new shaft recently sunk on the property, which assays as high as [illegible] per ton.

Humboldt County

The Seven Troughs Coalition Mining Co. is remodeling its mill. [illegible] battery, a Dexter [illegible], and a cyanide plant are to be added, and numerous improvements in the present equipment made.

Lincoln County

The Day Bristol Consolidated Mining Co. has been formed to take over the holdings of the Nevada Utah company and the Bristol Consolidated Mines & Smelting Co. The capital is $10,000,000 in shares of $10 each. Ernest R. Woakes is president and general manager. The Day and Bristol properties adjoin, being on opposite sides of the mountain. The plan of development is to continue the workings of the Day adit through the mountain to connect with the workings of the Bristol. The early workings of the Bristol extend down to the 800-ft. level, and the extension of the Day adit will add to this 800 to 1000 ft. more, giving a total depth of 1600 to 1800 ft. The work on the Day adit will be resumed at once, and when completed will form an ideal outlet for the Bristol [illegible] which will be loaded on the cars at the Day [illegible] of the long haul previously necessary to market the ore. This advantage will make possible the handling at a good profit the immense amount of low grade ore in the Bristol workings which has heretofore been [illegible]. The Pioche Pacific Railroad Co. has also been [illegible] by the same group of men that control this new merger. A new 12-mile line will be built between Pioche and Royal City.

Nye County

The Tonopah-Belmont has struck a good orebody on the [illegible] level, approximately 1300 ft. deep, and has started work on a crosscut south from the shaft. This is the deepest point at which work has been conducted. It is said that [illegible] is being found in the [illegible] of the White Caps at Manhattan. A lease is being worked by F. W. [illegible] and associates of [illegible], who have lately [illegible]. [illegible]

OREGON

[illegible] County

settled by a decree in favor of the mortgagees. Some time ago the property was sold for $85,000. Fifty thousand dollars was paid in cash and the remainder of the purchase price was held in abeyance subject to notes covering the premises. The property has been operated for many years. The mine has plenty of water and machinery, and is well equipped. Before the sale the mine had been leased for three years to J. R. Harvey. The property consists of 1500 acres, all of which has been patented.

SOUTH DAKOTA

Pennington County

Development work in the mine of the Harvest Mining Co., near Pactola, has been temporarily suspended pending arrangements for the installation of necessary machinery. The company, in which Pittsburg people principally are interested, and of which Frank Sherman has had the management, has been doing some systematic development work and has accomplished a great deal, considering the amount of money expended.

UTAH

Salt Lake County

Some recent figures have credited the Utah Copper Co.'s mines with having 203,800,000 tons of copper ore actually developed, with the probability of having not less than 250,000,000 tons of ore in the mines, which, on an assumed average saving of copper of but 1%, would yield 5,000,000,000 lb. of metallic copper. The life of the property is estimated at 35 to 40 years on the basis of a 20,000-ton daily output, which would give a gross annual production of 140,000,000 lb. of copper.

Juab County

An important discovery is reported as having been made in the [illegible] Beck mine in Tintic district. The discovery was made on the [illegible] level, some distance north of the shaft. The ore carries 30% lead with some silver, and is being shipped. From 60 to 70 tons of ore is being shipped from the [illegible] to the United States smelter, that nets about $2 per ton. The [illegible] has been shipping ore running [illegible] and nearly [illegible] lead. The shipments for [illegible] are expected to reach 30 cars. The Gold Chain mine is making some improvements to its surface equipment, including a second compressor. The United [illegible] has a hoisting plant [illegible] the Buckeye, and is equipped to sink 1000 feet.

WASHINGTON

Ferry County

Special Correspondence.—The [illegible] company has shipped three carloads of ore from a [illegible] at a depth [illegible]. [illegible]

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Oscar Hershey is at Juneau, Alaska.

Charles Butters has gone to London.

H. J. Callahan is at Treadwell, Alaska.

L. H. F. [illegible] has been at Butte recently.

John D. Ryan was at Great Falls recently.

Heinrich Ries is on his way to San Francisco.

H. Foster Bain was at Juneau and has gone to Valdez, Alaska.

Falcon Joslin has gone to Fairbanks, Alaska, for the summer.

Frank Keyes, of the [illegible] Gold Mines Co., is at Portland, Oregon.

Tom C. Parker, of Cortez, Nevada, was in San Francisco Monday.

F. A. Hammersmith has returned to San Francisco from Treadwell, Alaska.

J. C. Roberts has returned to Salt Lake City from the Spring Valley oilfields.

W. H. Weed is at Butte in the interests of the Butte Ballaklava Copper Company.

W. H. Storms has returned to Berkeley from an examination of the Rawhide mine, near Towles, California.

E. H. Benjamin has returned to San Francisco from an extended tour through the Eastern cities of the United States.

Philip Argall has returned to Denver, having suffered no further injury in the wreck of the *Spokane* than the loss of baggage.

Whitman Symmes, superintendent of the Union Con. and Mexican mines, has returned to Virginia City, Nevada, from San Francisco.

Arthur J. Hoskin is at Alma, where with **A. B. Patton** and **C. E. Smith**, he is engaged in a study of that district for the Colorado Geological Survey.

Raymond C. Benner, of the University of Arizona, is doing exploration work this summer for Mackenzie & Mann, in the province of Ontario, Canada.

F. H. Probert was at the Ray Central, and is now at the Cactus at Bellevue, Arizona. He will next visit the La Caridad mine at Nacozari, Sonora.

Nelson Dickerman, for the past year assistant to **Newton Cleaveland**, general manager of the Natomas Consolidated, has been appointed superintendent for the Kirtley Creek Gold Dredging Co., at Salmon, Idaho.

Jesse J. MacDonald has been detained in Colorado on professional business. He is now on his way to Victor, Cripple Creek, and Denver, and will leave there July 15 for San Francisco, stopping at Salt Lake City.

Copper Producers' Association Report

The monthly report of the Copper Producers' Association was in all respects rather favorable, the most noteworthy feature being a decrease of over 8,500,000 lb. in stock on hand compared with the previous month. Production for June was some 2,000,000 lb. less than for May. Domestic deliveries fell off almost 3,000,000 lb., but this was more than offset by an increase of almost 9,500,000 lb. in export. The detailed statement follows: Stock of marketable copper of all kinds on hand at all points in the United States June 1 is 165,995,932 lb. Production of marketable copper in the United States from all domestic and foreign sources during June, 124,554,312 lb. Deliveries of marketable copper of all kinds on hand at all points during July, 157,437,164 pounds.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

NATURE OF OIL AND GAS—LEASE

Oil and gas while in the earth are unlike solid minerals in that they are not subject to ownership from the soil; and accordingly a lease or grant of the oil and gas is in effect a grant not of the oil that is in the ground, but of such a part as the lessee may find, and such a lease passes no estate that can be the subject of ejectment or other real action.

Kolachny *v.* Galbreath, (Okla.) 110 Pacific, 902.

INJURY TO EMPLOYEE IN GYPSUM MINE

The duty of a master to furnish a safe working place for his servant to perform his work does not apply to a person employed in a gypsum mine to break the rock after it has been blasted.

Strepanski *v.* Grand Rapids Plaster Co., (Mich.) 127 Northwestern, 706.

INJURY TO ZINC MINER—EVIDENCE

A person employed as a mucker in a zinc mine was injured by an explosion of a 'missed shot.' In an action for injuries a question to a witness as to how many accidents occurred during a period of three years was properly excluded, and the ruling was harmless where the mine owner was permitted to show that missed shots frequently happened in the mine, as accidents from other causes were immaterial.

Hochshultz *v.* Potosi Zinc Co., (Nev.) 110 Pacific, 713.

CONTRACT FOR PURCHASE OF MINING CLAIM

A contract for the sale of mining claims and stipulating that such claims and all machinery placed thereon in working the mine shall be the property of the vendor until the purchase price is paid, and providing that the purchaser shall work and develop the mine and extract ores and appropriate the proceeds, gives such purchaser the right to prospect and develop the mines, but he can not commit waste or remove from the place any property constituting a part of the realty other than the ore so mined. In such case the machinery on the claim for use in working the mines becomes fixtures attached to the mine, and such machinery can not be attached by the creditor of the purchaser while the purchase price remains unpaid.

Conde v. Sweeney, (Cal.) 110 Pacific, 973.

ACTION ON COAL LEASE—AFFIDAVIT OF DEFENSE

In an action by a lessor to recover the value of coal mined from a small tract of land forming part of a larger tract of coal lands operated under a lease from the plaintiff's predecessor in title to an assignor of the defendant company, the complaint set forth a copy of the lease, the rights of the plaintiff thereunder, the rights and liability of the defendant company, the provision for the payment of royalty, the possession by the defendant of the tract under the lease, the mining of the coal therefrom, and its refusal to account or pay for the coal mined. The complaint also showed a chain of title from the commonwealth to the plaintiff. The defendant by its affidavit of defense admitted the existence of the lease and its possession, but alleged that the tract in question did not belong to the plaintiff or the original lessor, and that it purchased the tract from other parties after the date of the lease, and denied that it obtained any right thereto under the lease, but showed no chain of title in the defendant from the commonwealth. Such affidavit of defense was held to be deficient, and that it was not enough for the defendant to make a bald assertion and that it had a title in fee simple to the land in dispute, without setting forth the chain of title upon which it relied.

Lazarus *v.* Lehigh & Wilkesbarre Coal Co., (Penn.) 77 Atlantic, 817. July 1910.

Daniels Saftey Blasting Cap

There have been many efforts of late years to improve the ordinary detonating cap and at the same time to retain simplicity. The Daniels Safety Blasting Cap is being put on the market with the claim that it fulfills all the requirements of safety, is waterproof, will not crimp, and that misfires will not occur. On account of the Daniels cap having a slight shoulder within ½ in. of the top, a question on one or two occasions has been prompted regarding its insertion into the stick of dynamite. It is as readily placed into the stick as any ordinary cap, to the shoulder, which is all the distance necessary, and is the distance thoroughly in accord with the recommendations of the U. S. Government, that "when a fuse and detonator are used in loading, care should be taken that the detonator is not completely buried in the explosive, for as the fuse burns and fire rushes from its end some of it may blow out over the top of the detonator and set fire to the explosive about it before the detonator is set off. This has been a common cause of inferior and dangerous explosions."

Full information concerning the Daniels cap will be given by the manufacturers, Daniels Safety Mining Cap Mfg. Co., 333 Postal Telegraph building, Chicago.

EDITORIAL

A FEDERAL income tax law, though it has met with favor, can not be enacted this year, as the number of States which have endorsed the amendment is but thirty one, thirty five being required.

USING FIRE to fight fire is a traditional method of procedure, and a bill has accordingly been introduced in the German Reichstag to create a government monopoly of the oil business, in order to forestall private monopoly.

THE WATER-SUPPLY of New York is some forty million gallons less than at this time last year. New securities issued during the last six months amount to $180,000,000 more than in the same period of 1910. Find the hydraulic equivalent of one share.

SMALLPOX at Dawson has led to a strict quarantine. Passengers for Fairbanks and points down the Yukon are being transferred from boat to boat in the river, without entering the town. The requirement that all persons entering Alaska shall be vaccinated has, however, been rescinded except in the case of passengers traveling second class.

THE TREATY between Great Britain and Japan, recently renewed for a further ten-year period, provides that neither country shall be called upon to engage in war with a nation with which an arbitration treaty is in force. This has little more than academic value, for it was not within the bounds of possibility that the material interests involved in the alliance of the Anglo-Saxon and Oriental would ever have prevailed to bring on conflict between Great Britain and the United States. Business is business—but blood is thicker than water.

THE RAND is as unfailing a source of interest as of gold. During June the production rose above all previous levels, with the stupendous total for the month of 684,300 ounces, and the end is not yet. On a following page we have the pleasure of presenting an abstract of the James Forrest Lecture for 1911, recently delivered before the Institution of Civil Engineers. Mr. F. H. Hatch has been so closely identified with the advance of Rand practice that his presentation of present accomplishment and prophecies of progress is of unusual interest.

MUTUAL BANK insurance has been advocated at a recent meeting of the Wisconsin Bankers' Association, and it was proposed to organize a corporation for that purpose. Mr. Albert J. Beveridge has pointed out the advantages of the Canadian system of banking, where the increased use of credit and business confidence offers an advantage over our own more restricted methods comparable to the advance which the latter shows over the Chinese system of accepting coins only at what is practically a bullion valuation. The United States has grown enormously in the last hundred years, and the clothing provided for the boy often proves but ill-adapted to the needs of the man.

HOT WAVES are sources of much discomfort, and the one which has recently swept over the Central and Eastern United States has been extraordinarily oppressive, so much so that manufacturing and business houses were temporarily closed in some cities. In others, ice sold for ten times its usual price, and in all the toll of deaths among the children of the poor has been heavy.

BRITISH COLUMBIA has proved so attractive a field for American capital that our British cousins have felt some alarm. Some years since, Mr. A. R. Calquhoun prophesied that British Columbia was destined to produce a superior race of Englishmen, but Oriental immigration and American capital seem to have complicated the progress of orthogenesis. The most interesting situation of recent years was that of the past month in London. The Coronation attracted universal attention, while the Imperial Conference had but little interest for press and public. Yet the most loyal Briton would perforce admit that the relative national importance of the two events is exactly in reverse ratio. Great Britain's children have grown to the stature of manhood; their needs of a right demand a hearing. The new spirit in Imperial policy is evidenced by the Australian resolution providing that the rights of any Dominion shall not be infringed by a conspiracy of other Dominions. Oversea problems do not always admit the solution most readily applied at home. Canadians and Australians have met the forces of nature and tamed them to their service; their problems of larger development will be as adequately solved.

BUSINESS GEOLOGY, as distinguished from economic geology, is the term suggested by a friend to the well directed underground study of mineral deposits. The scientist does not scruple to sacrifice time, money, and health in his search for truth; the business man, seeking to apply truth to material ends, properly weighs the value of all three. Often a careful study of a situation will reveal methods by which all essential information can be obtained at but a fraction of the cost of the most obvious method of search. Mapping is an art that is unobtrusive, lacking the dramatic features of driving drifts and cross-cuts, or the sinking of diamond-drill holes. Yet often by careful mapping more accurate and illuminating information can be obtained than by the physical method; the more so if the geological engineer can not personally examine each bit of evidence disclosed by exploratory work. Significant features may thus be overlooked, and a large part of the value of the work lost. An old aphorism runs, "A poor workman always complains of his tools." Conversely, poor tools, skilfully applied, will produce astonishingly good results. The demands of business call for the maximum of production, the last horse-power of the engine, the last cubic yard of the dredge and steam-shovel, and maximum results from the minimum of work.

The Porcupine Fire

Last week the series of fires which had been devastating the province of Ontario culminated in an outbreak which has swept a large area centring about Porcupine. The early reports of loss of life were, as usual, much exaggerated, but many died in the effort to save property in the path of the flames. Those who took refuge in mine workings were suffocated by the gases of combustion; others took refuge in the lake and were drowned. The loss of surface equipment has apparently been almost complete; reports from the Dome, where the fire seems to have raged most fiercely, being to the effect that only the heavy portions of machinery, mortars, tube-mill shells, and large pumps, survived the flames, while the heavy Merrill presses were almost uninjured, the concrete foundations having suffered more. The Hollinger mill had already been destroyed by a previous fire, so that only the progress made in rebuilding has there been lost. At the other properties losses are heavy, but since no deep shafts have yet been sunk, exploration being confined to drilling and surface work, the loss is not so serious as it would have been at a later period of development. Like most disasters, it is not without its compensating advantages, for the area thus cleared will be easier to prospect, though this has been dearly bought. No word has yet been received as to the amount of damage which the railroad has suffered, an important factor in forecasting the effect of the fire upon the development of the area. Not improbably reconstruction will hinge upon ability to secure timber; the local supply has been destroyed, and much must be done before another winter lends its aid to the northern method of getting out lumber. Reconstruction must, therefore, depend upon lumber shipped from stock over the railroad, which will add greatly to the expense of rebuilding. Porcupine, though its possibilities were, like those of all new mining districts, greatly exaggerated at the beginning of prospecting, possesses deposits of demonstrated value, of which the development will be but hindered by the unfortunate outbreaks of forest fire. The undergrowth having been burned away, subsequent fires can scarcely occur, so that further damage seems now remote.

The Mexican Unrest

The situation in Mexico, from a commercial standpoint, is now quite as serious as at any time during the revolution. While hostilities were in progress every effort was made to prevent unnecessary interference with the conduct of business, and it is indeed remarkable how successful these efforts were. With the advent of peace more disturbed conditions have arisen, strikes have been declared, and large and important plants have been obliged to close. This is but a natural outcome of a civil war, as was instanced by the disturbed conditions during the reconstruction period following our own Civil War. A strong hand is needed to control the situation; during a period of readjustment this can not always be instantly applied where needed. The slaughter of the Chinese at Torreon is an indication of one of the chief causes of Mexican unrest. In many parts of Mexico, trading is in the hands of Chinese merchants, and large industries are in the hands of foreign investors, backed by foreign capital. It is but natural that Mexicans, seeing the growth resulting from foreign initiative, should feel pangs of jealousy, one of the most human of vices. It is no less ill-advised, however. The development of natural wealth by the citizens of a country is the best course to follow, but lacking local initiative and capital, development by outside capital and energy is better than to have it lie dormant for an indefinite period. No one would seriously contend that it would be good policy for a man to bury a million dollars in the ground, to be dug up by his grandchildren. He should securely invest it, rather, so that the grandchildren may receive it, tripled by its accrued profits. Yet there are not lacking those who advocate the holding of natural wealth until it can be developed in accordance with theoretic standards of efficiency. This is not a defence of reckless squandering of natural resources, but rather an attempt to point out the possibility of erring upon both sides of the line. Foreign enterprise in Mexico has not been an economic loss to the Republic; out of it has come the schooling of the natives in methods of industry and an increase of knowledge of resources and methods of exploitation, that is cheaply purchased at the expense of dividends returned to foreign shareholders. The profits from the increased amount of money in circulation and more steady employment, may easily be greater than those resulting from exploitation of natural resources by other methods. Much the same problem is faced by the mine owner whose work upon a small scale affords him but a small margin of profit. It is only natural that when, after having transferred a controlling interest in his mine for a substantial consideration, he beholds large profits accruing to others, he should exhibit a tendency to overlook the fact that his own profits are much greater than before. Mexico is not a tree with but one peach upon it, great fields for exploitation by native *entrepreneurs* still exist, and the wealth brought to Mexico by foreign enterprise will be a welcome asset in their development.

The development of foreign enterprise in Mexico offers a curious parallel to the growth of foreign organisms in the body, the antitoxin developed in this case being the funded knowledge of the Mexican people which has accrued through their intercourse with foreigners. Americans and English have brought with them an atmosphere of progress, and an air of enlightenment, that being breathed, must needs have marked effect. From it has arisen a demand for greater political and industrial freedom that, making itself heard but uncertainly at first, has now become unmistakable. In the adjustment to new conditions some discomfort will be felt; Republics and children alike are subject to 'growing pains.' The best interests of Mexico are not to be found in the hampering of foreign enterprise, nor is it likely, judging from previous experience, that the real leaders of Mexico will mistakenly believe the line of progress to be in that direction.

Merging Professional Societies

Consolidation of the Mining and Metallurgical Society and of the American Institute of Mining Engineers is now under consideration, committees having been appointed from the two societies to discuss the matter. On many accounts it is to be hoped that a feasible plan of uniting the two organizations may result from the negotiations. We have recently reviewed the work of the Mining and Metallurgical Society and the newer plans for the American Institute of Mining Engineers. It is clear that the council of the Institute is now willing, to a large degree, at least, to take up the work, neglect of which led to the formation of the new society. Whether the whole program of the latter can be in some manner incorporated into that of the Institute is not certain, but we see no insuperable difficulties. The Mining and Metallurgical Society has attempted three things in particular: the setting of higher standards of membership, the promotion of acquaintance and coöperation, and the provision of means for formulating and expressing opinion in reference to public matters affecting the profession. The Institute, by providing for the organization of local sections, has frankly adopted one of the essential features of the younger society. In maintaining a distinction, however nominal it has actually become, between members and associates, it recognizes differences in grade of membership. It would not seem foreign to its constitution to establish still further grades, such as are recognized by the majority of the leading professional societies. An engineer who has served seven years 'in a position of responsibility' may fittingly be called upon to assume larger responsibilities in a professional society, and his opinion is entitled to more weight than is that of a young graduate, or any of those whose main activity is in lines but secondarily related to mining; such as civil, mechanical, or electrical engineering proper, manufacture and sale of machinery, selling mining securities, or practising mining, etc. There should be a place in the Institute for all these, and indeed, for everyone connected with mining, but there should also be some gradation of responsibility and authority corresponding to experience and demonstrated ability. If some plan be adopted, and many suggest themselves, of bringing together out of the large membership of the Institute those who by experience and training are better qualified to express an opinion, no harm can come to the Institute and great good may result to the country and the profession by providing means for formulating and announcing such opinions. At present any such action is specifically prohibited by the constitution of the Institute, but if it be agreed that the action is desirable, the constitution can easily be amended. It is not certain that the particular plan adopted by the Mining and Metallurgical Society is the best, but with the experience of the last three years as a guide, a satisfactory scheme should be evolved. It is well known that if, three years ago, the council of the Institute had been willing to adopt its present attitude, the Mining and Metallurgical Society would not have been formed. In bringing the older institution to adopt the essentials of their program, its projectors and supporters will do a greater piece of work than that of organizing and maintaining a new society. We believe the Institute can and should adopt the three essential features of the plan of the Mining and Metallurgical Society. That being done, the two should promptly be joined. If the object be accomplished, there can be no good in maintaining an unnecessary organization, but the members of the Mining and Metallurgical Society are entitled to insist upon the essentials of their program being adopted; the form and name are unimportant. Among various proposals for methods of merging the two societies, it has been suggested that the Institute adopt the existing local sections of the Mining and Metallurgical Society and provide for additional sections as demanded. That each section add to its membership as it will, but that no one be elected member of the local section who is not first a member of the Institute, and second, who does not have all the present qualifications for membership in the Mining and Metallurgical Society. The basis of this plan is the fact that the bond of union in a National society is less close than is a local one which meets frequently and brings its members into intimate contact. A man may readily have associates in a large society that he would not care to know intimately and meet frequently at dinner. It is undemocratic, but it is human nature. There is little question that the principal benefit that has come to members of the Mining and Metallurgical Society has flowed from the small, frequent, and intimate meetings of the local sections. If all the present membership of the Institute resident in any given district is to become at once entitled to membership in the existing local organizations, their character will be entirely changed. Whether for better or worse no one may surely predicate. We have no desire to embarrass the excellent committees now having the matter under consideration by advocating any specific plan. We would, however, urge the union of the societies, since otherwise rivalry and its perils seem ultimately inevitable.

As we are about to go to press, word is received that the joint committee has recommended affiliation to the extent of joint meetings, both of the parent organizations and of local sections, a closer union having been prevented by the insistence of the Mining and Metallurgical Society upon preserving its identity and organization. It is to be regretted that this has proved to be the case, though it, too, is human nature. It is not impossible that a period of joint action in the manner proposed may demonstrate that a merger is feasible, after all, or other lines of progress may develop. Some good has been accomplished.

The Rand Gold-Mining Industry and its Future

By F. H. Hatch

*One important result of the perfecting of the slime-treatment process, on the Rand, has been the introduction of fine grinding in tube-mills,[1] with consequent increased extraction and shortened treatment period. Further, the adoption of tube-mills has modified the function of the stamp-mill. The stamp-mill, which formerly was not only the sole means employed for the comminution of the ore (excepting, of course, a preliminary reduction in jaw-crushers), but also performed the function of an amalgamating machine, by the introduction of mercury into the mortar-boxes, is now, in most modern practice, restricted to a single stage in a continuous series of crushing operations. **The researches of Caldecott and other members of the** Mines Trials Committee, have shown that the maximum diameter permissible for the battery-feed is $1\frac{3}{4}$ in., and that tube-mills are most efficient when fed with ore discharged through a 9-mesh battery-screen having apertures of 0.27 in., or say $\frac{1}{4}$ in. The effective range of the stamp-mill is, therefore, from $1\frac{3}{4}$ to $\frac{1}{4}$ in. As a result, stamps are no longer employed for fine crushing, and amalgamation in the mortar-boxes has been completely abolished; even plate-amalgamation in front of the stamp-mills has in many cases been done away with. In the most modern mills of the Rand the plate area has been much reduced.[2] Some enthusiasts have gone so far as to suggest that amalgamation might be dispensed with altogether, and the gold equally efficiently, and more economically, recovered by an all-cyanide process, in which the ore would be initially crushed in cyanide solution, instead of water. But the difficulty, which at present appears insurmountable, is to find a means **of giving the coarse particles** of gold a sufficiently long **treatment to effect complete solution without unduly delaying the whole process.**

In the newest plants the amalgamating tables are assembled, **together with the precipitation boxes for the cyanide** solution, in a separate building (known as the reduction-house) to which the tube-mill pulp and the enriched cyanide solutions are conducted. In this building the gold is recovered, away from grease and oil, and under conditions which render amalgam-stealing (so serious a source of leakage in the past) practically impossible. Furthermore, the running time is increased, since the stamps no longer **have to be hung up while the plates are being dressed.**

Concurrently with the limitation of the effective range of the stamp-mill, the weight of individual stamps has been increased by lengthening the heads, until, with the 2000-lb. stamp of the new mill of the City Deep mine, the economic limit of the cam-lifted gravity stamp appears to have been reached. The advantages of heavy over light stamps are thus summarized by Caldecott:[3] (1) Reduction of initial capital expenditure in erecting a lesser number of stamps and a smaller building to contain them. (2) Less shafting, belts, and other moving parts to maintain. (3) Less labor for dressing plates, lubricating moving parts, changing screens, and other work incidental to milling operations. **The capital charge of a modern reduction plant per ton** milled is one-third of what it was fifteen years ago, and the total ore-treatment cost is about 3s. 6d. per ton, the recovery being from 93 to 96%, according to the grade of the ore.

The stamp-duty (or tonnage crushed per stamp in 24 hr.), which twenty years ago, in the days of the 900-lb. stamp and fine-mesh discharge screening, did not exceed 3 tons, has gradually grown to an average of 7.45 tons for the whole Rand in 1910; and recent experiments have shown that by crushing to an aperture of 0.284 in. and by introducing an elimination screen to 'by-pass' the fine material from the rock-breakers direct to the tube-mills, it can be raised to as much as 26 tons per stamp.[4] W. A. Caldecott and E. H. Johnson now propose to break the mill ore-feed down to $\frac{3}{4}$ in. cube (maximum) and to separate 50% of the total for direct tube-milling.[5] This will still further increase the stamp-duty. It is obvious that under the conditions now obtaining, 'stamp-duty' has come to have very little meaning as a measure of milling capacity. The bulk of the work is done by tube-mills. In most modern plants one tube-mill (22 by $5\frac{1}{2}$ ft.) is being installed to every ten heavy stamps; and the latter only reduce 30% of the mill ore-feed to the required fineness.

MAP OF SOUTH AFRICAN GOLDFIELDS.

Now that the stamp-mill has been shown to be a crushing machine, representing only one stage in a series of successive comminuting operations, namely, (1) by rock-breakers, (2) by heavy stamps, (3) by tube-mills, it may be questioned[6] whether the work of the stamps (reduction, say, from 1 in. to $\frac{1}{4}$ in.) could not be equally well done either by rolls or by roller-mills of the Chilean type, or perhaps by a combination of both. This combination is favored in the United States. According to Philip Argall, 6-ft. **Chilean mills running at 33 r.p.m., on Cripple Creek** ores, **will reduce 4 tons per hour, 60% of which will pass a** 150-mesh (0.003-in.) aperture, the feed having been previously rolled to pass a $\frac{3}{8}$-in. aperture. In this case, rolls **and Chilean mills do the work of stamps and tube-mills on the Rand.**

The charge is sometimes made that the Rand metallurgists are unduly conservative, and that they are averse to the introduction of new processes, which may even have been shown to be successful elsewhere. But this conservatism is justified; the scale of operations on the Rand is so enormous that even minor changes in existing practice cannot be risked, without prolonged investigation and actual trial, under regular working conditions on the spot. The seriousness of even a small loss per ton, which might result from an unwise change of practice, is shown by the fact that on one of the largest plants a difference of one-tenth of 1 dwt per ton is equivalent to £18,000 worth of gold per annum. Before leaving this part of the subject, I will give some details of one of the latest mills erected on the Rand, which will serve to illustrate the methods employed for the mechanical handling of the ore at the surface.

[5] Letter of W. A. Caldecott to the author.

[6] This question has been raised by Philip Argall, *Eng. & Min. Journal*, Jan. 7, 1911, p. 44. See also H. Bayldon, 'Notes on Chilean Mills,' Inst. Min. Met. Bull. Bull. 75, 1910, p. 21, and S. J. Speak, *ibid.* Bull. 77, 1910, p. 5.

The City Deep mill is designed to handle 65,000 tons of ore per month, and is equipped with two hundred 2000-lb. stamps and nine 22 by 5½ ft. tube-mills, each unit of ten stamps being operated by a 50-hp. motor, and each tube-mill by a 100-hp. motor. The ore from the mine, delivered at the shaft-head in 5-ton skips, is divided into two classes by screening through grizzlies, the bars of which are set about 2¼ in. apart; the fine material is conveyed by a 20-in. belt direct to the main ore-bin, the coarse is taken by four 30-in. inclined sorting belts to the crushers, which are placed on the top of the main ore-bin, each belt feeding three 12 by 24-in. jaw crushers. The return portion of each sorting belt receives the rejected 'waste' and delivers it to a 20-in. belt (common to the four sorting belts) which conveys it to the waste-dump. The main ore-bin, which has a capacity of 1000 tons and is constructed of reinforced concrete, discharges through heavy doors, operated by compressed air, into 40-ton trucks for transport to the mill. The ore train is drawn by a 25-ton electric locomotive, operating, through overhead transmission, on the 2000-volt, 50-cycle, 3-phase current furnished by the power company. The trucks are fitted with automatic discharge doors.

In the stamp battery the ore is crushed to pass a 10-mesh discharge screen. The resulting pulp, after elevation by a 12-in. Robeson-Davidson sand pump, is classified in cones, and the coarse product delivered to the tube-mills. The product from the tube-mills, together with the overflow from the classifying cones, is conducted to amalgamating tables in the gold-recovery house. In this house are also placed the extractor boxes for the enriched cyanide solution, the clean-up machinery, and the refinery; so that all the operations connected with the recovery of the gold are performed in one building under the immediate supervision of the ore-reduction officer. The pulp from the amalgamating tables is again elevated by a Robeson pump and classified, the sand being collected in six vats[8] of reinforced concrete. A 24-in. conveyor-belt running under the centre line of these vats, takes the sand, excavated from them by a Blaisdell excavator, elevates it and delivers it by means of a belt, running at right angles, to the top of the sand-leaching plant, which comprises two rows of six vats[9] each. The sand is fed in by a Blaisdell distributor, and after leaching is discharged by a Blaisdell excavator through central chutes to two 24-in. conveyor-belts, one under each row of vats. A short cross-belt delivers it to a 24-in. inclined belt, which conveys it to the residue-dump. This belt is carried on a steel cantilever frame, the end of which is 100 ft. above the surface of the ground. The slimes are collected in four conical-bottom collectors[10] built of reinforced concrete. They are treated in two steel conical-bottom air-agitation vats, 32 ft. diameter and 38 ft. deep, and washed in eight steel conical-bottom wash vats, 40 ft. in diameter by 16½ ft. and 24½ ft. deep.

In the plant just described it will be observed that from the moment the ore is delivered at the shaft-head until the residues, containing only 5% of the original gold content, are finally deposited on the dump, the various products are conveyed from point to point, either by water, moving under the influence of gravity supplemented by sludge-pumps, or by purely mechanical appliances. In other words, native labor has been practically eliminated from the surface operations of the City Deep mine.

The search after labor-saving devices has been forced on the mine-owners by the fact that, in spite of a substantial growth, the supply of native labor has never equaled the demand, a position which has been accentuated by the repatriation of the Chinese. Shortly before the outbreak of the Boer War in 1899, the natives employed in the gold mines numbered 97,000. In January 1903, six months after peace had been declared, the number was 44,000. In January 1904 it had risen to 68,000, and by January 1905 to 83,000. In January 1910 it reached 163,000, and in January 1911 185,000. The number of natives employed in the gold mines at the end of April this year was 194,328, the largest number of colored laborers ever employed on the Witwatersrand mines. As to the present requirements, I cannot do better than quote from H. H. Webb's report to the Consolidated Gold Fields, dated October 1, 1910. In estimating for the next twelve months he writes: "To make up the present shortage in the operating mines and fulfil the requirements of the expanding companies, amalgamations, and new companies coming on, will call for probably another 70,000 natives at least, in addition to those already employed."

NATIVE LABORERS RESTING ON SUNDAY.

Efforts are being made to attract the native to the mines by improving the conditions under which he lives, both on and off shift. One important innovation has been the curtailment of night-work. Thus, in the mines under the control of the Consolidated Gold Fields, only 7.4% of the total colored laborers working underground at the end of 1910 were employed on night shift. This method of working the mine with one instead of two shifts has been found to have many advantages, from both a hygienic and an economic point of view. To mention only one, the condition of the air in the mines has much improved by the limitation of machine-drilling and blasting to once in 24 hours; and by the fact that there is an interval of about 14 hours between shifts, during which the smoke can clear away and the workings cool down. Another step in the right direction has been the provision of shelters at the shaft-head, and the erection of covered ways between the shaft-head and the compound, for use in inclement weather,

[8] 50 ft. diameter by 10 ft. deep.

[9] The vats measure 56 ft. in diameter by 12 ft. deep, and are of steel set on a floor and supports of reinforced concrete.

[10] Of 60 ft. diameter by 10 ft. and 16 ft. deep.

The 'boys' come up from their work hot, tired, and dirty; the protection thus afforded them from the bitterly cold winds that blow during the winter months, and the warm shower bath that is now insisted on in many mines, will do much to mitigate the pneumonia scourge that used to be so prevalent among native miners on the Rand.

Efforts have been made to solve the dust problem underground. With few exceptions, the Witwatersrand mines are dry mines, and the processes of machine-drilling, blasting, and shoveling consequently create and distribute through the air great quantities of fine dust. Fortunately, the gold mines enjoy an important distinction from coal mines in regard to this phenomenon, owing to the fact that the dust is non-inflammable and therefore does not lead to explosions. But the inhalation of the dust-laden air causes a peculiar disease, known as miners' phthisis or silicosis, as it is also termed—a deadly complaint which is responsible for a high mortality among the white miners, and to a less degree among the native laborers. By the proper application of water at the point of origin, the formation of dust can be prevented to a large extent; and several ingenious devices have been invented for catching the dust from the upward holes, into which water cannot be poured from a can, in the manner usually adopted with downward holes.[11] The chief difficulty, however, appears to be to get the men to use the dust-arresters, and to water down the stopes and other working places after blasting. By better supervision and a stricter enforcement of regulations, such difficulties will doubtless be overcome; and, with the disappearance of this serious evil, the conditions under which the men work underground will be scarcely less healthy than on the surface.

This brings me to the question of ventilation. In the early days of the Rand, and, indeed, until quite recently, it has not been found necessary to employ any artificial system of ventilation, the numerous shafts and outlets to the surface of the outcrop mines having sufficed to maintain an ample supply of fresh air. But with deeper levels (the Village Deep mine is already working at a vertical depth of 4000 ft.), fewer communications with the surface, and an increased rock temperature, artificial ventilation is destined to play an ever more and more important part in the future. Stuart Martin[12] gives it as his opinion that it will be impossible to work the deep levels economically without carefully thought-out schemes of ventilation, and that to secure success it will be necessary to have shafts with small frictional resistance and large air space, and to carry the air current through special ventilating roads.

The quantity of pure air to be supplied per minute, per man employed underground, is fixed by law at 70 cu. ft. This being a standard difficult to enforce, the South African Mining Regulations Commission, in a report published in 1910, proposes, as a substitute, the quality standard of a maximum of 20 parts by volume of carbon dioxide per 10,000 parts of air. Of this, 4 parts is an allowance for the CO_2 normally present in the atmosphere, 3 parts are allowed for the CO_2 produced by the burning of candles, and there is a further allowance of 5 parts for the CO_2 possibly given off from the country rock, leaving 8 parts per 10,000 as a legal limit for the noxious CO_2 due to the vitiation of the air by blasting, human emanations, etc. Under the proposed regulations, provision is to be made on each mine for a permanently up-cast and a permanently down-cast shaft, by the use of ventilating fans or otherwise, and the current of fresh air so produced is to be split by regulating doors at every level, where work is carried on, in proportion to its requirements. Further, the courses of pure supply and foul return are to be kept distinct by bratticing; and short circuiting is to be prevented by disused drifts and stopes.

The ventilation problem has already been seriously attacked on the Rand, and ventilating fans, varying in capacity from 50,000 cu. ft. per minute, at 1-in. water gauge, to 250,000 cu. ft. at 4-in. water gauge, have been installed at the East Rand Proprietary, at the Simmer Deep, at the Village Deep, at the Langlaagte Royal shaft of the Crown mines, and at several other mines of the Eckstein-Rand mines group. In splitting the air-current, the numerous dikes of igneous rock that traverse the Witwatersrand mines in a north and south direction (across the strike), can be made to serve as natural brattices, since they divide the mines into air-tight compartments. The levels which penetrate these dikes must be permanently closed, or, if used for tramming purposes, closed by double swinging-doors.

The ventilation of the mines is hampered by the small air-space and large frictional resistance of the rectangular timbered shafts at present in use on the Rand. For this reason many of the deeper shafts of the future will, no doubt, be of the circular type, with either brick or concrete lining, as is the common practice in the collieries of this country.[13] Main levels and underground inclined shafts will also be driven in the foot-wall. These will serve as intakes for the air-current, and, being in solid ground, will reduce the loss of air by short-circuiting to a minimum. Since these main ventilating roads, instead of following the irregular course of the reef-plane, are driven straight, they will also be admirably adapted for cheap mechanical transport.[14]

The ore broken in the stopes has, in the past, been trammed by hand on light rails, from the stoping-boxes to the loading stations at the shaft, in cars of from 12 to 16 cu. ft. capacity. When the ore was being transported on every level, through tortuous and badly graded roads of the customary small dimensions, scarcely any other method was possible. It is true that the late Wager Bradford, some few years ago, did attempt the introduction, at the Langlaagte Deep, of a mono-rail system of tramming; and it was also tried by E. J. Way at the New Kleinfontein mine. It has not, however, been generally adopted, on account of the expense of installation.

Under the changed conditions now prevailing on the Rand, due to the enormously increased size of the properties brought about by recent amalgamations, and the consequent possibility of concentrating a large output at fewer main hoisting shafts than before,[15] the evolution of an entirely new system of underground transport is being accomplished. It is becoming recognized that the rock, broken in the stopes, can only be economically dealt with by handling it on a few main haulage-levels situated at great intervals apart and driven straight, from point to point, in the foot-wall of the reef. The rock mined above each haulage-level can be delivered through vertical or inclined chutes, and should it be necessary to feed the haulage with rock mined below the level, such rock can be raised through inclined roads by mechanical haulage or electric hoists.[16] These main haulage-roads (which, as already explained, are intended to serve also as the intake of the fresh-air current) can, on account of their economic importance, be constructed of large dimensions. They can also be carefully graded and equipped with heavy rails. Such a system is being carried into effect at the Crown mines, where the two main hoisting-shafts are to be connected at a vertical depth of 2200 ft., by a main haulage-level 14½ ft. wide. This gallery is being driven, in the foot-wall of the reef, from one end of the property to

---

[11] Mr. Aymard's device for this purpose promises to be successful.

[12] *Journal* Chem. Met. and Min. Soc., S. A., Vol. XI, 1910, p. 214.

[13] Already a circular shaft of large dimensions is being sunk on the New Modderfontein mine.

[14] See H. Stewart Martin, Chem. Met. and Min. Soc., S. A., Vol. XI, 1910, p. 214.

[15] Thus the Crown mines (late Crown Reef, Crown Deep, Robinson Central Deep, South Rand, Langlaagte Deep, Langlaagte Royal, and Paarl Central) are concentrating on two shafts the hoisting done, prior to the amalgamation, through seven shafts. Rand Mines Report for 1910.

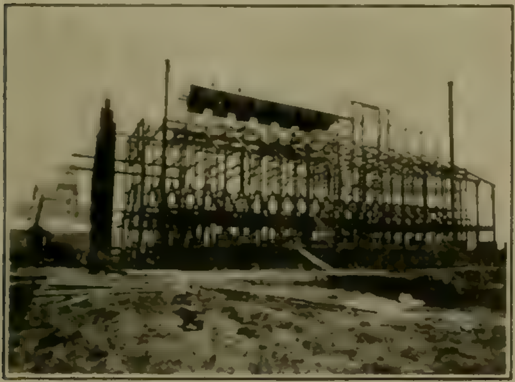
[illegible] and the plant [illegible] by [illegible] it will be operated by an electrically driven [illegible] so [illegible] that the ore may be hoisted [illegible] shaft [illegible] it is estimated that the [illegible] will be [illegible] from 9000 to 10,000 tons of ore per diem.[17] Other [illegible] will be driven [illegible] of [illegible] to take the [illegible] Similar work is being done at the New Modderfontein [illegible] and at the Modder B [illegible] system will become general.

Endless-rope haulage [illegible] be used with advantage where the roads are straight; where there are many curves it is preferable to draw the ore trains either by petrol locomotives as at the [illegible] Deep, or by electric locomotives as at the [illegible] Proprietary mine. With the latter system some difficulty is experienced in completely insulating the electric current lines, the raw and careless native [illegible] The bold policy of driving these straight haulage roads in the foot-wall of the reef, even before the orebody has been blocked out, as is being done at the Crown, New Modderfontein, and Modder B mines, is an interesting indication of the confidence of the Rand engineers in the relative permanence of the gold content of the banket [illegible], as compared with quartz veins. The big intervals at which the reef levels are now being driven is another indication of the same confidence.[19]



MILL OF BRAKPAN MINES LTD.

CROWN MINES MILL.

The handling of the broken rock in the stopes is, from an economic point of view, scarcely less important than haulage on the levels. Everything depends on the angle of dip of the reef. In many of the outcrop mines of the Central Rand the high dip of the reef permitted the rock broken in the stopes to find its way by gravity to the tramming level, where it was drawn off as required from the stope-bins; but with the dips of from 25° to 30° obtaining in most of the deep-level mines, the broken rock requires to be assisted down the stope floors by shoveling. Only in the extreme East Rand, where the reef lies very flat (dipping at from 8 to 10°) is it possible to fill the cars at the stope-faces and to run them thence direct to the tramming levels. Shoveling is uneconomical, and moreover, is detrimental to health on account of the dust it raises. Consequently, several attempts have been made to substitute for it some conveyor system of handling the broken rock. E. J. Way has described the method he employed at the New Kleinfontein mine, by which a very large reduction in the number of unskilled laborers employed in shoveling [illegible] in the stopes was effected.[20] Mr. Way's stope-conveyors are shaking chutes consisting of steel plates 18 in. wide and 8 ft. long, the ends simply [illegible] according to the [illegible] of the stope, from [illegible] ft. They are suspended by short chains from the roof and [illegible] to the working face of the stope, and are operated by one or more men, according to their length, who pull at ropes attached to the upper ends of the conveyors. Kept in motion by the jerks, the ore slides down the conveyor and is discharged at the lower end into stope-bins, or direct into cars at the tramming level. Being easily dismantled, the conveyors can be taken down before and put up after each blast. When the working face has advanced about 6 ft. they are hung in a new position close to the face of the stopes, a series of small holes being drilled in the roof to take the hook-bolts carrying the chains. Many of these shaking chutes are now in use on the Rand, and are usually hung from a rope stretched taut along the roof. Each chute length is attached by chains hooked on to clips permanently fastened to the rope at proper intervals. Before blasting, the chutes are unhooked from the rope, which, in most cases, can be left on the roof. When shifting to a new place, it is only necessary to attach the rope to the roof, by drilling a few holes in line, without having to keep the exact distance of the chute lengths.[21]

The breaking of the ore in the stopes is performed to a very large extent by hammer and jumper drill work, and since this work requires the largest proportion of the native labor employed on the Rand, it constitutes a serious problem, not only on account of the perennial difficulty of obtaining a sufficient supply of natives, but also on account of the time lost in lowering and raising such great numbers of men. The problem can be solved only by increasing the efficiency of the native laborer; or, in other words, by increasing the tonnage broken per native employed. Labor-saving devices for handling the ore when broken have already been dealt with. It remains to discuss the efficacy of machine-drills in stoping, as compared with hand labor.

(To be continued.)

TALC is usually marketed as rough from the mine, sawed into slabs, and made up into manufactured objects such as laundry tubs, or ground into powder. In 1910, 69% of the talc was ground and 21% made into slabs and manufactured. The product of New York is practically all ground. Vermont ranks second and produces both ground talc and soapstone. Virginia, the third in rank, produces some ground talc, but a large amount of soapstone, in the production of which it outranks all other States.

---

[17] The greatest output of any existing shaft on the Rand today probably does not exceed 2000 tons per diem.

[18] E. J. Way, in a letter to the author, states that he is experimenting, with considerable success, on a conveyor-belt system of transporting ore. Each section of belt will be driven by a separate motor and will feed on to the next section by means of a specially designed chute.

[19] Thus in the New Modderfontein mine the reef-levels will be driven at 500 to 600 ft. apart, and the main haulage-levels, in the foot-wall of the reef, at 1700 to 2000 ft. apart. (Chairman's speech attached to Report for the year 1910.)

[20] Proc. Inst. Mech. Eng., 1907, p. 989. With seventy conveyors in use, Mr. Way employed 420 less men in the stopes than when shifting the rock by shoveling.

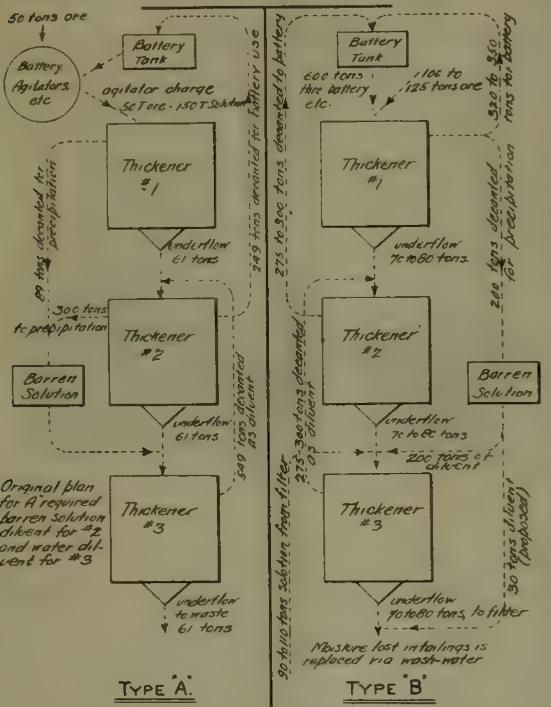
Continuous Decantation

By Donald F. Irwin

Within recent years there has been a noticeable tendency toward continuous methods in metallurgy. In the cyaniding of slime, which is, in practically every case, accomplished by treatment of successive charges, an excellent field is offered for continuous processes, since the usual three units of the plant, collector, agitator, and filter, receive and discharge pulp intermittently. Furthermore, the widespread use of sliming methods offers a large field for experiment on this point.

I consider a fair standard of continuous operation to be the ability of any unit machine to receive, treat, and discharge its full proportion of mill pulp at all times, without temporarily diverting into another vat any portion thereof at any time. Successful continuous collection and decantation was developed by J. V. N. Dorr in South Dakota, and continuous agitation is well exemplified by the Esperanza mill under M. H. Kuryla. There are other machines than the Dorr thickener and the continuous battery of Pachuca tanks claiming to perform the same work, but it is conceded that these machines were the pioneers.



50 tons ore
Battery Agitators etc
Battery Tank
agitator charge 50 T ore - 150 T Solution
249 tons decanted for battery use
89 tons decanted for precipitation
Thickener #1
underflow 61 tons
300 tons to precipitation
Thickener #2
Barren Solution
underflow 61 tons
549 tons decanted as diluent
Original plan for A required barren solution diluent for #2 and water diluent for #3
Thickener #3
underflow to waste 61 tons
Type "A"
275 to 300 tons decanted to battery
Battery Tank
600 tons thru battery etc.
100 to 125 tons ore
320 to 350 tons for battery
Thickener #1
underflow 70 to 80 tons
200 tons decanted for precipitation
Thickener #2
Barren Solution
underflow 70 to 80 tons
275-300 tons decanted as diluent
200 tons of diluent
90 to 110 tons solution from filter
Thickener #3
30 tons diluent (proposed)
underflow 70 to 80 tons, to filter
Moisture lost in tailings is replaced via wash-water
Type "B"

Using the various types of equipment mentioned, it is now possible, at least theoretically, to feed ore in at the crusher, make a few adjustments, and then recline in the shade, while the plant operates automatically. For two reasons, at least, it is not possible at once to install such equipment in every plant. (1) There is very little information available on this subject, as there are few plants operating which embody the continuous process throughout. (2) Considerations of time and treatment and general suitability of the ore must be observed. If feasible, the continuous process is wonderfully attractive on the grounds of simplicity and cheapness, and with the belief that any information, though incomplete, will be of interest, some data follow, on the plant with which I am familiar, which uses this method.

As a basis of comparison, I have taken a similar scheme of treatment proposed by Ferdinand McCann, which appeared in the *Engineering and Mining Journal*, October 2, 1909. To facilitate comparison, a parallel diagram of both plants is appended. In both plants the fundamental idea is successive decantation, thickening, and increasing dilution through a tandem set of three Dorr thickeners. I will refer to the plant suggested by Mr. McCann as type A, and the other as type B. Both schemes of treatment require crushing in solution. Type B differs from A, in that the entire mill-flow goes to No. 1 thickener, instead of a thickened charge from an intermediate collector and agitator. This is done because the ready solubility of the metallic contents obviates necessity for agitation, although for the usual type of ore, an agitating equipment would doubtless be required.

For the foregoing reason, the quantity of solution, taken from No. 1 thickener for precipitation in type A is smaller than type B, but per ton of dry ore treated is nearly the same—1.8 tons in the one case, 2 tons in the other. However, type A requires additional precipitation of low-grade solution from No. 2 thickener—possibly 300 tons. Hence precipitated solution per ton of dry ore treated is 7.8 tons, at least, and McCann advocated a total of 11 tons. In type A, under the original plan, the reduction in value of solutions, between each tank (assuming perfect dilution) is 90%, a figure not attained in B, where figures based on routine operation show a reduction of 40.8% between No. 1 and No. 2, and 43.5% between No. 2 and No. 3.

The average content of the solutions decanted from No. 1 thickener in A and B respectively were 143 gm. of silver and $1.52 gold. The apparently less efficient work of B is explained by the diluent for No. 2 being the decanted solution from No. 3, instead of barren solution, and the diluent for No. 3 being barren solution, of satisfactorily low tenor, but not absolutely barren. Further, a vacuum-filter followed No. 3 in type B, the filtered solution being used as an additional diluent for the pulp flowing into No. 3 thickener.

In an article by L. B. Eames in the *Mexican Mining Journal*, September 1910, continuous decantation is discussed theoretically, and attention is called to possible additional dissolving of metals during the passage of pulp through the tanks. This is shown to be true in B; solution tonnage and assays for the period quoted showing $26 additional dissolved daily in No. 2 and $15.80 in No. 3. A substitution of a fourth thickener for the vacuum-filter in No. 3 would render the plant simpler in operation, but the additional indicated extraction of gold while passing through would be very small. Reckoning from the work of three thickeners it would be negligible, and the grade of solution would be little more than 10c. per ton, and possibly less. A well regulated thickener will discharge quartz slime pulp with 40 to 45% moisture, and a vacuum-filter of the leaf type will filter a cake carrying 30 to 35% moisture, requiring considerable additional water to sluice it away, in most cases probably not less than 50% in all. The value of replacing a fourth thickener by a filter can only be obtained by noting the daily loss of dissolved gold and cyanide in the underflow from the thickener, say 40 tons of solution, carrying 8 to 10c. gold and cyanide, or a total daily loss of about $12, say $4500 yearly, for a 100 to 120-ton plant. Against this can be set down the greater water consumption of a filter-plant (a substantial consideration in many places), the initial cost of the filter, and more rapid depreciation of a filter-plant. Perfect washing of cake is assumed. There is no doubt that a cheap, efficient, and compact filter could be used to advantage, but it must be all that, and with low power and labor requirements besides, for the power, labor, and maintenance cost on a thickener is very small indeed.

McCann makes no reference to the manner of transfer of pulp and solution in type A; this is doubtless the point needing the most care in operation. At plant B decanted solutions were raised by air-lifts and the pulp by diaphragm pumps. The dilution of the thickened pulp can be effectually done by placing baffles in the launder receiving pulp and solution. A small centrifugal pump handles the battery solution, and a small triplex pump raises the gold solution. In a large plant of this kind, handling several hundred tons of ore daily, units of 100 to 120 tons could be arranged as in type A or B, but with each tank placed successively lower than the preceding one. This would aid in pulp transfer, the limiting case would be when all tanks are discharged by gravity.

Transfer of the thickened pulp at a minimum expense for power and attendance is sought in several ways: one plant used air-lifts, another centrifugal pumps, a third diaphragm pumps, and a fourth discharges into sumps from which the pulp is drawn by bucket-elevators. Regulation of pulp and solution flow is not quickly disturbed when valves are once properly set and pumps are speeded correctly. Barring accidents, type B is a very smooth working plant. All the work of operation and current repairs is done by one man and a helper, a saving of one or two men over the average slime plant employing solution man, filter man, and pump man. On the other hand, should an accident occur, it needs immediate attention, and no long delay is admissible. In general, this type of plant is simple in operation, with low labor, power, and maintenance costs, and, when metallurgists generally are familiar with it, should become a popular and standard method of slime treatment.

Mine Bulkheads

By William H. Storms

In the development of a mine it not infrequently happens that a large quantity of water is unexpectedly encountered, and it becomes desirable, if not positively necessary, to stop the inrush of water, for the reason that the pump or other drainage machinery of the mine is inadequate to handle it, or it may be considered too expensive to continue to pump if the flow of water can be shut off. In such exigencies the construction of a bulkhead in that portion of the mine where the heavy flow of water has been found, is usually resorted to.

There is a wide divergence of opinion as to what sort of bulkhead is best suited to such conditions. Bulkheads have been successfully constructed of timber, of stone, of brick, of concrete, and of various combinations of these materials. Any of them will serve the purpose, provided the rock at the site of the bulkhead is sufficiently firm, impervious to water, and the static pressure is not too great. Where the column of water is high, the form of the construction, as well as the materials from which the dam is to be built, is of importance. Where the head is low, say less than 20 ft., a dam built of walls of a double thickness of 2-in. plank, with a centre of clay well tamped, will suffice in most cases; but if the head be much greater, something more substantial than plank must be employed. Clay is only useful in forming an impervious stratum; for, to be serviceable, it must have the most substantial kind of backing, timber, masonry, or concrete. It must be remembered that it is not so much the quantity of water back of the bulkhead as it is the height of the water column, for it is quite easy to build a dam which would hold back a flow of a hundred cubic feet a minute which has a head of only 10 ft., while to hold back a flow of but 5 cu. ft. per minute which has a static head of 300 ft. or more would require a very substantial structure. It is head, not volume, that counts.

In preparing to construct a mine bulkhead it is necessary, first, to select a place in the drift or cross-cut where the rocks are firm, and where the cross-sectional area of the opening is not too great. A dam in loose or fissured rock would prove to be unserviceable, if not a positive element of danger. Then, too, the smaller the cross-section the more feasible will the successful construction of the bulkhead be. Having selected as suitable a place as can be found for the purpose, the next thing to decide upon is the form of the dam. Under moderate heads, such as might be expected to develop within 60 or 80 ft. of the surface, a dam having a plane front and back will usually be strong enough for all purposes, if it be sufficiently thick; but if the site of the dam be more than 100 ft. below the surface, or there is any possibility that a column of water more than 100 ft high may develop, then it will be safer to construct the dam in the form of an arch, with the concave side outward. Channels from 18 to 40 in. deep should be cut in the top, bottom, and sides of the opening where the bulkhead is to be built, in order to give the dam a firm anchorage. The depth to which this channel is cut must be left to the judgment of the engineer in charge, or to whoever is to build it. In very firm hard rock it would be unnecessary to channel as deeply as in softer or fissured ground.

In cutting this channel the surrounding rock should be disturbed as little as possible. Heavy blasting must be avoided, as it is likely to shatter the surrounding rock so badly as to render the bulkhead useless, and perhaps even unsafe, should the water pressure become heavy. Some engineers prefer a wedge-shaped cut to a right-angled channel. The wedge cut is made so that it flares inwardly from the outer face of the dam. A mine-dam of this form, described by W. Kelly in Vol. XXVII, *Trans.* Amer. Inst. Min. Eng., was built in the Curry mine at Norway, Michigan. This dam was 780 ft. below the surface, and as it was not known to what height the column of water would rise, the dam and all pipes and fittings were designed to withstand a pressure of 350 lb. per square inch. The bulkhead was constructed of masonry, local sandstone being used, and great care taken that the joints were true, and that the pipes were properly placed. The wall was built in the form of an arch having a radius curve of 6 ft. and a thickness of 10 ft. The sides of the drift were trimmed out along lines approximately conforming to the radial lines of the arch at the sides of the dam, these lines being projected inward. This made the mass of masonry much wider and higher at the back than it was at the curved front. A 5-in. pipe fitted with a heavy flange was laid through the stone wall to drain the water under control, a suitable valve being provided for this purpose. A 20-in. pipe was similarly laid in the wall to serve the purpose of a manway. This was closed on the outside by a blind flange, 2½ in. thick, into which a small pipe was screwed and to which was attached a pressure gauge.

When the water pressure accumulated back of this dam it leaked so badly that the pipe was opened and the water allowed to drain off. A brick wall 22 in. thick was then built 26 in. beyond the inner face of the masonry bulkhead, and the space between filled with concrete, made of 4 parts of broken limestone, egg-size, and 3 parts cement mortar. The pipes were extended through this addition to the bulkhead, which was then 14 in. thick. Before closing the dam this time, three loads of horse manure were placed against the inner face of the brick wall, being held there by a partition of boards. After these precautions had been taken the bulkhead was found to be practically tight, although the pressure ran up to 277 lb. per square inch. This experience shows clearly the need for a very large factor for safety in the construction of mine bulkheads, particularly where the pressure is likely to be high. I have known of a number of mine dams that failed, from various causes, chiefly from insufficient strength, and which had to be rebuilt.

In the Juniper mine near Stent, California, a bulkhead was recently constructed in a foot-wall cross-cut at a depth of about 280 ft. below the surface, though it is probable that, owing to surface contour, the maximum head will never exceed 230 ft., which is equivalent to about 100 lb. pressure per square inch. This bulkhead is of concrete, and was built in the form of an arch, and is 4 ft. thick. Deep channels were cut in the top, bottom, and sides of the cross-cut, to secure a substantial anchorage for the concrete, which was then placed with care. A 6-in. pipe with a flange on the inner end was laid in the concrete, and a hopper-shaped manhole provided. To close this inwardly-flaring manhole, a tight-fitting door, made of two thicknesses of heavy timber bolted together at right angles, was hung on hinges. The door was made large enough to permit the passage of a small car, as it would be necessary to subsequently do mining in the area back of the dam. When the door was closed and drawn tight by means of bolts, it was discovered that the dam of concrete was itself practically impervious to water, few leaks developing, but through fissures in the surrounding rocks the water spurted with ever-increasing force as the column of water grew in height. About 30 cu. ft. of water per minute was flowing from the crosscut when the door was closed. Within a few hours the pressure was evidenced by the spurting of water through the rocks surrounding the dam, and the next day fully 10 cu. ft. per minute was passing the dam. To control this water a second dam will be built at a point about 60 ft. in front of the first one, and where the cross-section area is smaller and the rocks appear less fissured. This dam will also be of concrete.

In the construction of mine bulkheads that are to hold water, it is very necessary to not underestimate the quantity of water flowing past the site of the proposed dam, and to provide a pipe sufficiently large to carry all of it, and a little more. If a pipe larger than 5 or 6 in. diam. be required, it is better to put in two of smaller diameter than one large one, as the smaller pipes can be anchored with less difficulty, and it will be found later that if this suggestion be followed, no mistake will be made.

June Copper Review

By Misha E. Appelbaum

Throughout June copper continued to advance, on very large domestic buying and still more liberal purchases by European consumers. As a result, the market reached 12$\frac{5}{8}$c. for both lake and electrolytic. When the market reached this level, buying subsided somewhat and transactions took place at a slightly lower level, but at this writing, early in July, the market is again firmly entrenched on a 12$\frac{3}{8}$c. basis. The deliveries for the month of June showed an excellent European consumption, while the domestic deliveries were slightly less than in May; this, however, is usual during the month of June, for the principal consumers shut down for a few days to take an inventory at the end of the month.

The consumption for the month of July will very likely show a shrinkage, as, on account of the excessive heat, it has been impossible for the mills to run with full force, but the production, on the other hand, will also show a sharp shrinkage, as the output of the refineries will be materially lessened on account of climatic conditions. Inasmuch as Europe will, on account of its previous purchases, take a large quantity of copper during the month of July, I expect to see the surplus further reduced during the month by about 15,000,000 pounds.

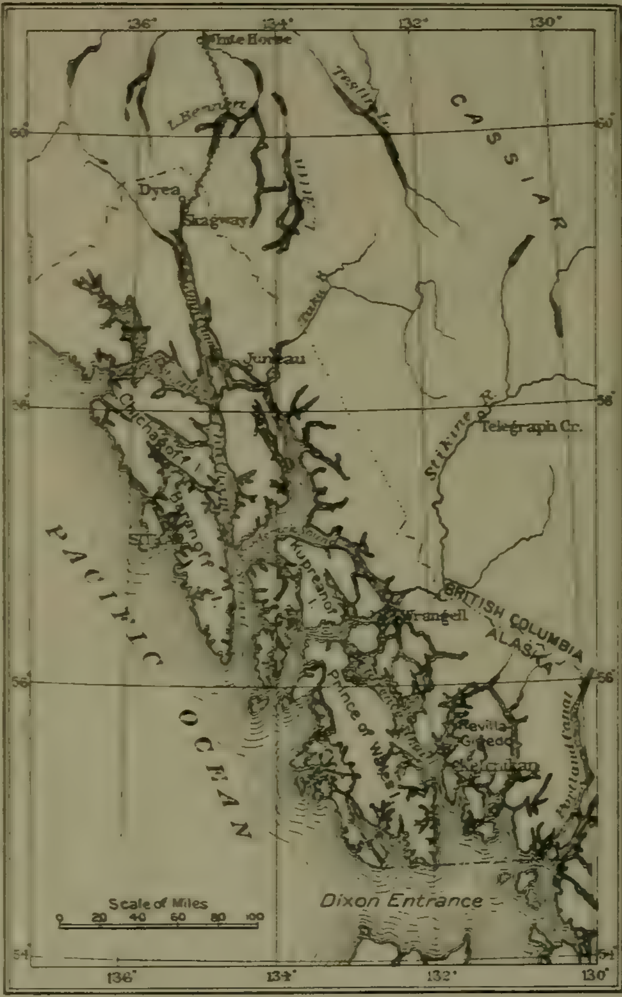
The surplus in this country on the first of July was 157,000,000 lb.; such a surplus is absolutely necessary to prevent a runaway market. The surplus in Europe has also been cut down materially and it would be possible to become enthusiastic over the prospects for higher prices were it not for the fact that production still continues at a record rate. Since the output of the new mines, though not very large, will add to the production, and small business has not yet assumed large proportions, I cannot see how the market can advance further, although, on the other hand, business prospects seem to be sufficiently encouraging to expect steady prices.

The consumption of compressed acetylene has become enormous in recent years. Small portable generators are not practicable in winter, as the water is apt to freeze, but a solution of acetone and acetylene will not freeze during the coldest weather. No automobile is considered complete without a cylinder of acetylene for lighting.

The Portland Canal District

By R. G. McConnell

*The Portland Canal district is situated in northern British Columbia, close to the Alaska boundary, at the head of Portland canal, one of the largest of the numerous fiords which indent the North Pacific coast. Portland canal cuts completely across the long granitic batholith which forms the central portion of the Coast range and reaches the mineralized sedimentary and intrusive rocks which border the batholith on the east. Bear river empties into the canal at its head, and the area examined includes the portion of the mineralized belt drained by that stream and its tributaries. Portland canal is a large deep inlet, easily navigable by the largest steamers. Stewart, the distributing point for the district, is situated at its head, and several steamship lines maintain regular communication between it and Prince Rupert, Vancouver, and other coast towns. A wagon-road has been built by the Provincial Government, from Stewart up Bear River valley to Bitter creek, a distance of about ten miles, and from it the principal showings are reached by trails constructed partly by the Government and partly by private companies. A railway up the valley is now being built.



MAP OF SOUTHEASTERN ALASKA.

The metalliferous character of the Portland Canal mining district was first discovered by a party of prospectors in

---

*Abstract from the Summary Report of the Department of Mines, Canada, 1911.

1898, the year of the great Klondike rush. They were searching for placer deposits, but failing to find pay gravel turned their attention to prospecting for quartz. The Roosevelt and other claims on the south fork of Bitter creek were staked in 1899, and the Mountain Boy and American Girl on American creek in 1902. The Alaskan boundary at that time had not been defined, and the claims were first staked under United States laws, but were subsequently re-staked and recorded in British Columbia. The Red Cliff, which could hardly escape the notice of prospectors as the croppings show up prominently on the mountain side, was first staked in 1898, and has lapsed and been re-staked several times, the last time in 1908. While some prospecting and staking were done year by year, little actual mining work was attempted until 1907, when the Portland Canal Mining Co. commenced development work on the Little Joe and Lucky Seven claims on Glacier creek. The success met drew the attention of miners to the district, and during the last three or four seasons prospectors have swarmed over it, and little ground from Stewart far up Bear River valley, which shows any signs of mineralization, is now left unstaked. Only a few of the claims have been even roughly prospected, and on only two, the properties of the Portland Canal and the Red Cliff mining companies, is development much advanced. A number of companies, however, commenced systematic work during the past season.

The Portland Canal mining district is situated in the heart of the Coast range, in a region of intense glaciation, and its topography, while still bold and striking, has been toned down by moving ice, and much of the original ruggedness removed. It has been heavily glaciated up to a height of fully 5500 ft. above the sea, and the mountain slopes, below this level, although usually very steep, often rising in sheer unscalable cliffs, are, as a rule, comparatively smooth, except where scored and broken by narrow canyons carved out, in post-glacial times, by streams plunging down from the perennial snow and icefields above. The district embraces a number of high mountain groups and mountain ridges, separated by the deep valleys of Bear river and its numerous tributaries, but usually coalescing around the heads of these streams. The principal mountain divisions include the long, rather even ridge separating Bear river and its tributary American creek from the Salmon; a group of mountains between American creek and the upper part of Bear river; a range of high sharp peaks known as the Cambria range[1] bordering the upper part of Bitter creek; a broken ridgy group culminating in Mt. Gladstone between the north fork of Bitter creek and Bear river, and a group of high, snow covered, rather flat topped elevations between Bitter and Glacier creeks, for the highest point of which the name Mt. Dickie[2] is proposed.

The long ridge west of Bear river has a general elevation of about 5000 ft., but is surmounted by occasional irregularly distributed rocky peaks, some of which attain a height of over 6000 ft. One of the most prominent of these, situated nearly opposite the mouth of Bitter creek, is known as Mt. Dolly. The sharp-crested, angular-peaked Cambria range, the wildest portion of the district, rises in places to an elevation of over 8000 ft., and Mt. Otter, the highest point, to an elevation of 8800 ft. Mt. Gladstone, the highest point in the range bordering the upper part of Bear river on the south, has an elevation of 6800 ft., and Mt. Dickie, between Glacier and Bitter creeks, an elevation of nearly 6600 ft. The snow-covered mountain group of which Mt. Dickie forms the centre is exceedingly precipitous on the Bitter creek side, but falls away in easier slopes toward Bear river and Glacier creek. The dominant features of the mountain landscape, viewed from one of the higher elevations, are the steep valley slopes, the jagged peaks of the Cambria range, and the prevalence above an elevation of 4500 ft. of vast fields of snow and ice. These either terminate in long lines of ice cliffs from which huge masses are constantly falling, or form glaciers which descend the mountain slopes for some distance, and are then replaced by roaring torrents often deeply hidden in rocky canyons.

The rocks and rock formations represented in the Portland Canal district are classified tentatively as follows, in order of relative age:

1. Glacial deposits.
2. Basic dikes.
3. Felsitic dikes.
4. Coast Range granitic rocks.
5. Diorites (?).
6. Nass formation (tuffs, agglomerates, etc.).
7. Bear River formation (complex series of greenstones).
8. Bitter Creek formation (dark argillites).

No fossils were found in the district, and the age of the formations is uncertain. The last three are cut by granitic rock and felsitic dikes, and are, therefore, older than the Coast Range batholith usually referred to as Jurassic.

Economic Geology.—The Portland Canal district is remarkable for the widespread character of the mineralization it has undergone. This is manifested not only by the number of concentrated metalliferous deposits of varying sizes scattered throughout the region, even though they are so numerous that practically the whole district has been staked, but also by changes in and additions to the principal rock formations themselves. Secondary iron pyrite is everywhere present, and silicification on an unusually large scale has taken place. Large areas—in one instance a whole mountain mass—have been altered by this process into hard cherty rocks.

The district is situated immediately east of the great group of granitic rocks which form the central portion of the Coast range, and its mineralization is doubtless due to this fact. During the granitic invasion, the neighboring rocks, both sedimentary and intrusive, were intruded by dikes, crushed and broken, and rendered permeable to emanations, probably mostly in the form of silicious waters from the cooling magma. These waters either originally held the various metals in solution or leached them out in passing through the various rocks encountered and deposited them when heat and pressure lessened. The whole district is probably underlain in depth by granitic rocks, as dikes and stocks are numerous everywhere.

The deposits of the district may be generally grouped into two classes:

1. Veins (mostly quartz).
2. Irregular, replacement deposits.

Quartz Veins.—The quartz veins occur mostly in the Bitter Creek argillites, but in some instances were found traversing the massive Bear River greenstones. In the argillites they follow, in most cases, long zones of fissuring and crushing, often of considerable width, which while enlarging and pinching at intervals along the strike, are on the whole fairly regular. The walls are straight and well-defined in places, in others ragged and irregular. The quartz filling varies greatly in purity in different veins and along different portions of the same vein. Fragments of the broken country rock are almost invariably present in some quantity, and in places the vein consists of alternating bands of quartz and argillite, or of a brecciated mass of argillite cemented together by quartz. In some instances the line of the vein is marked only by stringers and lenses of quartz distributed irregularly through the argillites. The veins, with few exceptions, have a general northerly trend, approximately parallel to the direction of the eastern edge of the neighboring granitic batholith and to the strike of the enclosing argillites. The dip is usually westward toward the granite at angles varying from 20° to nearly vertical.

While most of the veins are comparatively small, usually from 2 to 4 ft. in width, a number are exceedingly strong and very persistent. The most notable of these is the vein on which the Portland Canal company's mine is situated, south of Glacier creek. This vein, while it cannot be continuously followed, as some stretches are concealed and others are inaccessible, is traceable by a succession of outcrops, some of considerable length, all following the same general direction for a distance of over two miles, and probably extends across Glacier creek to the Sunbeam claim, a total distance of nearly four miles. The quartz filling may be interrupted in places, but it is practically certain that the line of disturbance is continuous. In places several parallel veins are present. The width of the vein is commensurate with its length, ranging from 10 to over 60 ft., and probably averaging 20 ft. in the outcrops seen. The strike of the vein is northerly, and the dip is westerly at low angles, usually about 30 degrees.

---

[1] Name proposed by miners interested in the vicinity.

[2] After the president of the Portland Canal Mining Company.

North of Glacier creek, the O. K., Portland Wonder, George E., and other claims are situated on veins following a line of strong fissuring, traceable for over a mile. On the George E., four well-defined veins, the largest 27 ft. in width, occur in the fissured zone. These veins are usually considered to be a continuation of the vein, or series of veins south of Glacier creek, but this, while probable, is not altogether certain, as the outcrops are separated by a concealed interval about half a mile in length. The dips in the veins north of Glacier creek are also somewhat steeper, and the direction is more easterly. Other large quartz veins occur on Bitter creek south of the Bromley glacier.

The principal metallic minerals in the large quartz veins are pyrite carrying gold, silver-bearing galena, zinc-blende, and occasionally notable quantities of native silver. Pyrite is always the most abundant mineral present, and in portions of the veins is often the only one. Where it occurs in masses it is usually associated with subordinate quantities of galena, and some blende. While practically only a beginning has so far been made in the exploration of the large quartz veins, enough has been done to show that the distribution of the metallic contents is extremely irregular. The veins are seldom entirely barren, and small bunches of ore are common, but concentrations large enough and rich enough to be of commercial value are rare. One such deposit is now being worked by the Portland Canal Mining Co., and others may be discovered as exploration proceeds. Several promising portions of the veins are now being investigated.

Small and medium-sized veins, that is, veins ranging from a few inches to 6 ft. in width, and occasionally even wider, are very common in the Bitter Creek slates, in the dioritic area at the head of Glacier creek, and also occur, though less frequently, in the Bear River greenstones, and in the granite. Some of these veins are very persistent, one on the middle fork of Glacier creek having been traced across three claims, and one on Hartley gulch for over 1000 ft. Few of them have been explored sufficiently to determine their extent. The gangue in the smaller veins is more varied than in the larger ones. Quartz is nearly always present, and a few of the veins consist entirely of that mineral. Others have calcite as the principal gangue, or a mixture of calcite and quartz, and occasionally the filling consists mostly of siderite.

The metallic content also shows great variation. In the dioritic area at the head of Glacier creek tetrahedrite in grains, bunches, and small lenses occurs in some of the veins, associated with galena, pyrite, blende, and stibnite. Lenses and stringers of nearly solid galena occur in veins at Bear River canyon, and at points east of American creek. Chalcopyrite, in bunches and lenses, usually accompanied by pyrite, blende, and galena, also occurs in a few croppings. The small veins, like the larger ones, are, as a rule, irregularly mineralized, shoots of ore, usually short, alternating with barren or comparatively barren stretches, and the bunchy character of the mineralization has already led to some disappointments. Very few of the veins, however, have had any considerable amount of work done on them, and a large number, some with promising outcrops of good ore, still await investigation.

Replacement Deposits.—In the massive and slightly schistose greenstones of the Bear River formation, the ore deposits occur characteristically in irregular, often ill-defined masses. A number of red patches, due to the oxidation of these masses, are plainly visible from the valley in the mountain slopes bordering Bear river and American creek. The shapes are variable, some are wide and blunt, others rounded or elliptical, and a few are elongated, resembling wide irregular veins. In some of their features these mineralized areas resemble contact metamorphic deposits, but the characteristic contact metamorphic minerals, such as garnet, epidote, augite, etc., which invariably accompany such deposits, are never present in quantity, and are usually altogether absent. Garnet, mostly in disseminated crystals, was seen at only two of the croppings visited. The gangue in the deposits is mostly the more or less altered country rock, although some quartz is usually present, and in places there is a considerable development of this mineral. Calcite and barite also occur, but are less common.

The deposits probably always occur in connection with lines of fissuring, or, as suggested by their irregular outlines, with broken areas, but this is not always evident. In some of them the relationship is plain, as they are bounded on one, or sometimes on both sides by fissures, and for portions of their courses, especially where the replacement is nearly complete, resemble, and practically are, veins. Traced farther, the space between the so-called walls becomes less well mineralized, and often passes into ordinary country rock. Transitions occur from this vein-like type, through occurrences partly bounded by walls, to others wholly lacking in definite boundaries other than those afforded by the gradual disappearance of the replacing minerals. The metallic minerals in the replacement deposits are generally similar to those in the veins, except that pyrrhotite is occasionally present in place of pyrite. The proportion of chalcopyrite is probably greater on the whole, and the proportion of galena less. Pyrite, often carrying some gold, is usually the principal mineral present. The pyrrhotite is always, so far as known, low grade. The associated minerals are chalcopyrite and galena in varying quantities, and usually a little blende. The chalcopyrite at the Red Cliff orebody, the only member of this class of deposits on which much development work has been done, is distributed in grains, bunches, and interbanded with pyrite through the whole mass of the lode, and forms a considerable part of it. In most of the occurrences examined, the copper and lead sulphides are present only in portions of the pyritized area, and in some are apparently absent altogether. The ultimate value of these large mineralized areas cannot safely be predicted: a number of them are inviting enough to warrant exploration, while others are hopelessly low grade, on the surface at least.

THE Hokkaido Colliery & Steamship Co. established a blast-furnace at Wanishi, Hokkaido, to produce pig iron to supply the Nippon Steel Works. Some 2,000,000 yen was invested in this establishment, and it was put into operation. The plan to use Hokkaido iron ore, which had been reported inexhaustible, was a complete failure, and there was trouble with the furnace, so business was suspended. Though repairs have been made, work has not been resumed. The ovens which furnished the coke used at this blast-furnace are five miles from Wanishi, which caused considerable inconvenience. It is now intended to establish the coke ovens in Wanishi, and the plant will again be started. As a supply of iron ore from Hokkaido cannot be depended on, the materials will be imported from China and Korea, as in the case of the steel works at Wakamatsu.

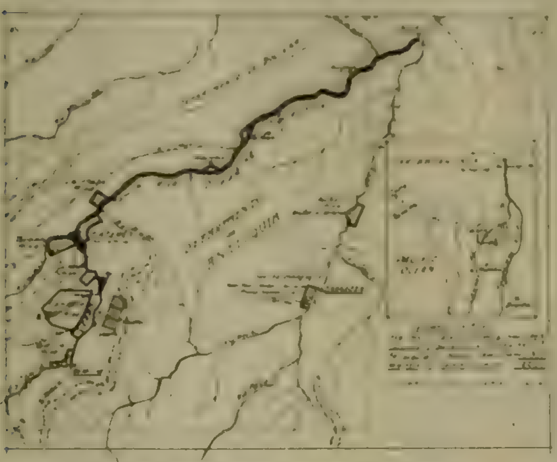
FLUORSPAR is a mineral of relatively low value as compared with the metallic ores mined under similar conditions in the West. Under the most favorable conditions, therefore, the margin of profit can never be expected to be large, and it requires exceptionally good management to conduct any spar operations profitably in the Western States. In 1909, 50,742 short tons of domestic fluorspar, including gravel, lump, and ground varieties, was marketed in the United States at an average value of $5.75 per short ton. Of this total, 40,808 short tons was sold as gravel and lump spar, at an average value of $4.72 per ton at the mines. Spar produced in Colorado and New Mexico sold unground at about the average price for the whole production of spar in the United States, including the ground variety.

Gold Dredging in Colombia

By Charles Janes

What are probably the first successful gold-dredging operations in Colombia are being carried on at the property of Mr. Pochet on the Nechi river, some distance below Zaragoza where the Pato mines, controlled by the Oroville Dredging Limited, are situated. These are shown on the accompanying map.

Mr. Pochet is operating a small dredge built in Belgium some years ago for another property, on which it proved unremunerative. The dredge, which is equipped with [illegible] ft. open-connected buckets, and operated under steam power, using wood fuel, was purchased by Mr. Pochet in 1910 and moved to its present situation. The following figures of operation are given by the management.



MAP OF CAUCA RIVER DISTRICT, COLOMBIA.

Pochet Dredge Operations. Seven Months

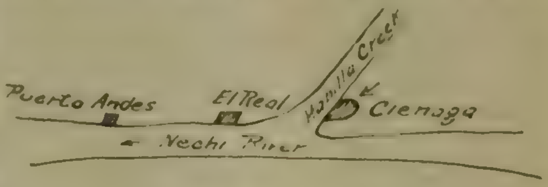
		Gm.
Clean up	August 9, 1910	8,000
	September 9	5,027
	October	9,115
	November	11,791
	December	10,300
	January	7,110
	February	11,592
	Total	62,935

Gold, average fineness	920
62,935 gm.	$38,200
Operating cost	13,200
Operating profit	$25,000

The expense for seven months, counting $400 per month for manager, and including labor and all supplies and repairs, was $13,200. The ground worked was estimated at 77,400 cu. yd., of an average depth of 27 ft. This indicates a yield of 49c. per cubic yard and a cost of 17c. per cubic yard. From February 7 to March 17, on account of low water on the Nechi river, they managed to get to bedrock, which was not possible during high water, and from 6200 yd. estimated to have been handled received $8700, or $1.24 per cubic yard. There was considerable loss of running time, hence the low yardage treated. The accompanying sketch gives an idea of the gravel in cross-section.

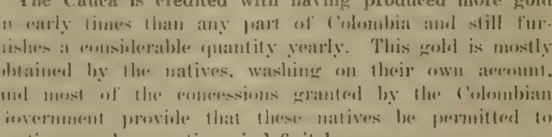
At the Pato mine of the Oroville Dredging Limited the new 8½-cu. ft., close-connected bucket dredge with steel hull, built by the Yuba Construction Co., is under construction. Most of the dredge parts are on the property at the present time, and the remainder are being brought in as fast as transportation facilities will permit. The property has over 400 acres of proved dredging ground containing [illegible] per cubic yard; the operating cost, according to recent statements of the management, will be under 8c. per cubic yard.

The Pato property was carefully prospected with Keystone drills by competent engineers, and was the first gold dredging in Colombia to be financed following sane methods of prospecting. Since the original report, it is stated that further areas have been proved, substantial buildings for the staff and workmen erected on California hill, which is 150 ft. in elevation above the river. Hydro-electric power will be used, though it is understood that it was found necessary to make a number of changes in the original plans of power installation and dam location. The operation of the dredge on this property is awaited with considerable interest by dredging men, and will mean much for the future of dredging operations in Colombia if it proves as successful as anticipated.



DREDGING GROUND, POCHET

One of the largest gold-mining concessions granted in Colombia is that of the Colombia Consolidated Goldfields, situated on the Cauca river from Caceres to the town of Nechi. This property was extensively prospected with Empire drills. The gravel is from 35 to 65 ft. deep, and financial arrangements have practically been completed for equipping and working the property on a large scale. In addition to the dredging ground there are considerable areas of gravel, from 25 to 125 ft. deep, that are said to be suitable for hydraulicking, plenty of water under good head and good dumping facilities being available. There are also a number of quartz veins on the concession, but on these, however, no development has as yet been attempted.



RIVER AND BENCH GRAVEL, NECHI RIVER.

The Cauca is credited with having produced more gold in early times than any part of Colombia and still furnishes a considerable quantity yearly. This gold is mostly obtained by the natives, washing on their own account, and most of the concessions granted by the Colombian Government provide that these natives be permitted to continue such operations indefinitely.

The western part of Colombia has recently been attracting considerable attention as a possible field for dredging operations. One company has a number of small parties investigating areas along the San Juan and tributaries of that river. Some years ago a dredge installation was made on the Atrato river near Quibdo, financed by Pittsburg and Philadelphia capital. Civil war interrupted the operations for a time, but it is understood, however, that they did not prove successful. This property is now under bond to New York interests, and is being examined with a view to installing a modern dredge. Other dredge installations have been made in Colombia, including one some distance south of the latter property. Information is not available at the present writing on these ventures, but it is understood that they were not a financial success.

The mining laws of Colombia are favorable to foreigners. The Government is now considered stable and anxious to help all legitimate mining enterprises as much as possible. There is an import tax of 1% upon all gold-mining machinery, and supplies are subjected to a small duty only. A placer claim is subject to a tax of $5 per claim annually, and in case of non-payment the mine is considered abandoned, and open for denouncement. Nothing is required by law in the way of annual labor on a claim, and until recently a mining property could be freed from all subsequent taxes by the payment of 20 years taxes, or $100 per claim in advance. This has been done with such properties as the Pato and Colombia Consolidated Goldfields. Mining claims have preferences to all timber and water rights in their vicinity, and in case of previous ownership of such rights, all questions are submitted to a board of appraisers. Some care should be exercised in taking up a property to see that both mining and agricultural rights are secured, otherwise some trouble may occur with the owner of agricultural rights in the future, especially when the mine becomes a producer.

The climate of Colombia naturally varies in different sections. Some districts are considered unhealthy for foreigners to live in, and in others Northerners have lived for a number of years without any ill effects. It may be said that many of the conditions under which miners must live are trying, but with proper precautions, such as suitable houses, clearing away the jungle in the neighborhood of living quarters, fighting the mosquito, good food, and a sane manner of living, there is no reason why health cannot be maintained. A strong constitution will be found a valuable asset for a Northern man going to any tropical country.

Historic Iron Deposits

Bulletin 470, of the United States Geological Survey, on the iron ores in the Montevallo-Columbiana region, Alabama, is of historic interest. Actual operations in this section were begun in 1844 with the construction of a furnace having a daily capacity of five tons of cold-blast charcoal pig iron, and work has been practically continuous since that time. The iron made here early acquired a high reputation, and as a result of a comparative test of Alabama, Georgia, and Tennessee irons made at Columbus, Georgia, in 1852, an order for 1000 tons was given, the largest ever placed in Alabama up to that time. A rolling mill was completed in Alabama in 1860, in which armor plates were made for the Confederate Government. The *Merrimac*, which for a time created such consternation among the Union warships and which later was a participant in the memorable battle with the *Monitor*, was armored with these plates. In 1863 a larger furnace was built, with a daily capacity of 30 tons. This was equipped with warm-blast ovens and was the first furnace to make warm-blast charcoal iron in Alabama. This furnace was burned in 1865 at the time of Wilson's raid. The output of the two furnaces at Shelby at the present time is about 25,000 tons per year.

June Production of the Rand

Recent advices are to the effect that a new record has been made by an average daily output of 22,810 oz. Remembering that June is a short month, the achievement is even more notable. The table below gives the average production in ounces per day, from January to June, for the last five years:

	1911.	1910.	1909.	1908.	1907.
January	21,100	19,400	19,840	18,070	17,340
February	21,780	20,560	20,180	19,350	17,620
March	21,800	19,600	19,600	18,540	17,370
April	22,230	20,630	20,230	18,860	17,900
May	22,100	20,450	20,140	18,770	17,050
June	22,810	20,830	20,570	19,160	16,180
6 mo. average	21,970	20,240	20,090	18,790	17,240

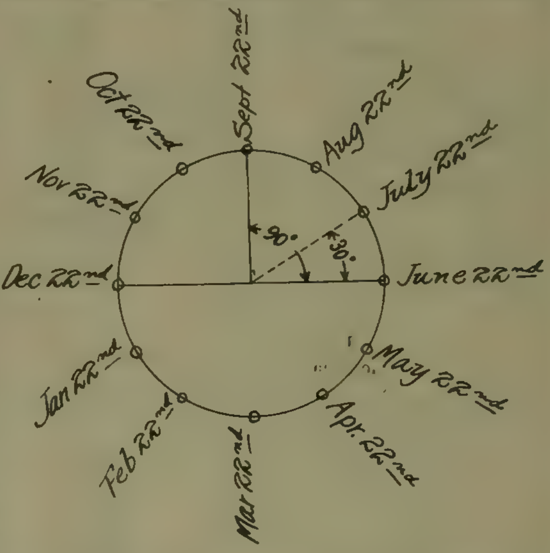
Azimuth Determinations Without an Ephemeris

By G. N. Pfeiffer

Descriptions have been published of methods of making observations on the sun for the meridian when either the date or the current year's ephemeris has been lost. A method of determining the meridian by equal altitudes, either of the sun or of any fixed star, under these difficulties, or when no ephemeris is available, is given below.

The method of finding the meridian by equal altitudes is simply to observe the azimuth and altitude of any fixed star at any time before it has passed the meridian and again when it has passed the meridian and has the same altitude as at the first observation. This second observation will be as much west of the meridian as the first observation was east of the meridian. In practice it is common to set the transit over a station, set a peg in line with the first observation, and to set another peg marking the second observation: bisecting this angle gives the meridian. As it is often inconvenient to make observations at night, this same method can be applied to the sun during the day if the correction is made for the changing declination of the sun. The change in declination between the two observations is added to the altitude when the sun is coming north, and subtracted from the altitude when the sun is going south. If no ephemeris is available, the hourly change in declination is not known. All surveyors should know that the hourly change on June 22 and December 22, when the sun is farthest from the equator, is practically nothing, while the hourly change on March 22 and September 22 is practically one minute of arc per hour of time, and it is almost as easy to remember that the hourly change is fifty seconds of arc per hour of time when the sun is one month from the equator; and thirty seconds of arc per hour of time when the sun is two months from the equator. This can be deduced in the following way: assume 12 months to represent the circumference of a circle whose radius is the greatest hourly change in declination, when the sun is over the equator. From June 22 to September 22 is 90°. The hourly change is from zero to the maximum in 90°, so it may be assumed that the change is according to the sine, without serious error. July 22 is one month, or 30°, from June 22, so the hourly change will be 60″, sine 30° = 30″, which is approximately correct.



To show how reliable the method is when the change in declination from the morning to the afternoon observation is added to the altitude for increasing north declination, I have made some calculations which are given below.

1	2	3	4	5	6	7.	8	9	10
44°30'	23°26' N	2 7"	64°	1hr. 12 5 min	52°1'6"	+4'22"	+17'30"	-3'44"	-15'3"
44°30'	23°26' N	2.7"	30°	4hr 11min	94°23'5"	+1'31"	+5'57"	-0'54"	-3'45"
44°30'	0°0'	59 3"	43°30'	1hr 0 7min	21°9'54"	+5'19"	+21'14"	-5'12"	-20'53"
44°30'	0°0'	59 3"	20°	4hr 5 3min.	69°20'34"	+1'36"	+6'22"	-1'13"	-4'47"
44°30'	23°26' S	2 0"	20°30'	1hr 1 3min.	15°0'46"	+5'14"	+20'57"	-5'14"	-21'01"
44°30'	23°26' S.	2. 0"	10°	3hr 4 1min.	42°9'26"	+1'56"	+7'49"	-1'40"	-6'40"

When making these calculations only six place logarithms were available, so some slight errors may exist.

Column 1. Latitude of the observation.

Column 2. Declination of the sun.

Column 3. Hourly change in declination of the sun.

Column 4. Altitude of the sun at the time of the observation.

Column 5. Time the sun is from the meridian.

Column 6. Bearing or azimuth of the sun.

Column 7. The error in the sun's azimuth when declination is taken 1′ too great.

Column 8. The error in the sun's azimuth when the declination is taken 4′ too great.

Column 9. The error in the sun's azimuth, when altitude is taken 1′ too great.

Column 10. The error in the sun's azimuth when altitude is taken 4′ too great.

Consider the third determination, the third line of the above table, made in latitude 44 30′ north about 11 a.m. local time. The altitude of the sun for the first observation was 40°30′ and a peg was set in the same vertical plane as the sun. Upon looking up the declination in the ephemeris it was found to be exactly zero and that the hourly change was 59.3″. From this the bearing of the peg set was calculated to be 21°9′54″ east of south. Suppose the sun did not change its declination; then when it again reached the same altitude of 43°30′, about 1 p.m. local time, it would be 21°9′54″ west of south. On the contrary, if at the time of the second observation the sun's declination was 0°1′ north and no allowance was made for this change, then the bearing of the second peg would be 21°15′13″ west of south, or an error of 5′19″; in the same way, if the declination was 0°4′ north the bearing of the second peg would be 21°31′8″ west of south, or an error of 21′14″. Since the hourly change is very nearly 1′ per hour, and the time between the observations was two hours the change in declination was practically 0°2′. The error was only ½ of 21′14″ or 10′37″, which gives a bearing of 21°20′31″ west of south. Again, assuming the sun does not change its declination, but that a mistake of 0°4′ was made in the altitude, setting off 43°34′ instead of 43°30′ for the afternoon observation, the sun would reach this altitude too soon by 20′53″, or when it has a bearing of 20°49′01″. In the same way, if the error in altitude were only 2′, then the horizontal error would be ½ of 20′53″ or 10′27″, which gives a bearing of 20°59′27″. Applying both errors simultaneously, their algebraic sum is 0′10″, or a bearing of 21°10′4″ west of south. Bisecting the angle between the pegs halves this error, the meridian as determined is 0′5″ west of south of the true meridian. This shows that a practical way of allowing for the change in declination is to increase the altitude by the same amount when the sun is coming north.

The drawbacks to this method are:

(*a*) When taken on the sun it is not correct unless allowance is made for the change in declination.

(*b*) The sun cannot be used in high latitudes.

(*c*) It is often not convenient to wait in one spot to make the second observation.

(*d*) If a star is used the second observation may be made on some other star by mistake.

(*e*) The sun or star may be obscured by a cloud at the time of the second observation.

The advantages are:

(*a*) Except in high latitudes an observation on the sun affords the degree of accuracy required by engineers.

(*b*) When the observation is made at night several stars can be used independently as a check.

(*c*) No corrections are necessary from standard time to mean local time and from mean local time to apparent local time.

(*d*) In high latitudes a star can be used.

(*e*) When no ephemeris is at hand this is a convenient method.

Platoro, Colorado

By Charles S. Barnes

This district has many large well defined fissure veins, as much as 34 ft. of ore running $8 to $11 per ton in gold and silver (with streaks of high grade in shoots), that are now attracting the attention of mining men. Owing to the refractory nature of the ore, milling, until recently, has been out of the question, and only the ore from the 'high-grade streaks' could be handled. These have been mined on many properties, and ore shipped to the Denver smelters for treatment has returned as high as $300 to $800 per ton; one property alone having shipped $350,000 worth of ore, while others have shipped, in varying amounts, up to $200,000 worth. While this high-grade ore was being mined, thousands of tons of low-grade ore have been developed, one property having 500,000 tons of $11 ore. Owing to the isolation of this district and ignorance upon the part of the property owners regarding improvements in methods of treating refractory ores, the camp has been dormant for a number of years. But recent mill-tests show conclusively that a high recovery can be made by the use of cyanide treatment.

The best illustration of what can be accomplished by installing mills to treat these ores is shown by the success of the Liberty Bell company of Telluride, Colo., upon an ore that is similar in character and gold and silver content. Consequently, "where others have blazed the trail we can safely follow." Certain large properties are to resume operations on an extensive scale, just as soon as preliminaries can be arranged. Many other promising claims, with more or less development, can be had at reasonable prices. This district offers exceptional opportunities for capital, with its large bodies of low-grade milling ore, both developed and undeveloped.

Timber in West Africa

Much trouble is experienced in West Africa from the rapid rotting of timber. The foundations for stamp-mills are usually made of concrete as a base, but in the Wassau mill the mortar-blocks were of imported pitch pine, which speedily rotted, giving much trouble during the last two years' running. In other cases, such as the 50-stamp mill of the Taquah mine, the main base was of concrete, on which were laid cast-iron anvil-blocks to receive the mortar-boxes; the longitudinal sills, strake sills, mill-posts, and ore-bins were of wood. The mill started in July 1907, but the timbers are rapidly decaying, and indeed are now being replaced. The present manager is preparing to use steel girders and reinforced concrete in place of timber, so that when the full 50 stamps resume crushing there should be no further trouble about foundations during the life of the mill. Pine timbers last fairly well in West Africa, as in other regions, if they can be kept either quite dry or else completely under water, but as neither of these conditions can be fulfilled in a stamp-mill foundation, other material must be utilized in construction work. Even battery-posts fail quickly if made of wood, while the dampness in the ore is generally sufficient to ensure speedy destruction of a wooden bin. Local timber would be more enduring; Kaku, Kwisaba, and Odum furnish excellent wood, and might give much better results if the trees were 'rung' a year or so before felling, so that the timber could season in an erect position as it stands; but there is no doubt that steel and reinforced concrete will in the end prove most economical. It is found in ore-bins, for example, that pitch pine of 12 by 12 in. section usually rots completely in about four years. But there is no reason why the ore-bins both at the 'bank' and in the mill should not be constructed completely of steel. In all the principal mines the practice, until recently, has been to timber the shafts with 8 by 8-in. pitch pine, a custom which is still followed in some places, but steel sets are now being generally used with great advantage.

Excavation at the Panama Canal

*Some important changes have been made in the method of excavating hydraulically in the lower lockpit at Miraflores, and in the Canal prism south of that point. Heretofore, the plan has been to dislodge the material in the sides and at the bottom of the excavation by monitors, which sluiced it to where the dredge pumps, mounted on concrete barges, could lift it into the fill of the west dam, or elsewhere, as desired. This plan provided for settling the concrete barges into sumps, and it is owing principally to the difficulty experienced in getting the barges in a suitable working position that it has been decided to abandon them. Stumps and the trunks of old trees that had become buried in the soil covering the site of the hydraulic operations in the lower lock at some previous period were among the obstacles encountered in settling the barges effectively.

Under the new arrangement, sumps will be created to various depths in the area to be excavated, and the pumps removed to positions alongside. This will do away with any need for the three concrete barges built expressly for mounting the dredge pumps and motor equipment, and one of them has already been dynamited and removed. It is proposed to break up a second one due to the difficulty of getting it out of its present position, but the third may be removed and used elsewhere.

The depth has reached a stage that permits a change in the method of working the hydraulic monitors, or giants. Instead of directing the play of the water against the surface of the material, the process of undercutting, which will allow the overhead mass to fall in as the work proceeds, will, in future, be employed. Dredge pump No. 2 has been shipped to the Gorgona shops for repairs, and it is proposed to install temporarily in its place the relay pump originally purchased for relaying the material into the fill of the dam. The relay pump will be placed directly in front of Cocoli hill. The face of this hill contains a great many small boulders which the relay pump is particularly well adapted to handle, inasmuch as its impeller admits pieces of rock 8 inches in size, compared with 6-in. pieces, the maximum size handled by the other pumps. It is estimated that the greater proportion of the boulder material found in this locality can be sluiced and pumped out in this manner. The sump where the relay is to be situated will be the main one; it will be sunk to 55 ft. below sea-level, and the dredge pump will occupy a position on a bench alongside, about 25 ft. below sea-level.

---

*From the *Canal Record,* June 21, 1911.

Gold Deposits of Bokhara

St. Petersburg Correspondence

The question of the discovery of gold in the Russian Central Asiatic provinces, particularly in Turkestan and Bokhara, has cropped up as a matter of common interest from time to time. The Khanate of Bokhara has been most carefully investigated from this point of view, and important work has been carried on in the search for gold in that area by such men as B. A. Zhoravko-Tokorsky, Leva, S. L. Nikolai, and others. Turkestan has not been so carefully explored as Bokhara. The general impression was that from the information received as to the gold deposits of Turkestan, an important development of the gold industry in that area was not to be expected. Recently the tendency to stake out claims in Russian Turkestan has become brisker, and even St. Petersburg citizens have taken a lively interest in the possibilities of this area. It is said that, although the prospects are only moderate, there is a chance of a gold mining region being developed there.

At the conference that took place at the end of last year on the part of the Permanent Consultative Committee of Gold and Platinum Producers on the situation of the gold industry in Russia and the possibilities of further development, several persons stated that the industrial importance of the gold deposits in Turkestan could not be considered as definitely disproved, but that results of investigations in Bokhara have proved fairly satisfactory. It may be hoped that with the development of civilization and the clarifying of the political situation in that country, particularly with the introduction of means of communication, the gold industry will develop rapidly.

Readers of the *Mining and Scientific Press* will remember that a statement on the goldfields of Turkestan was published in these columns on October 1, 1910. Important gold deposits have been found in the Khanate of Bokhara by B. A. Zhoravko-Tokorsky, who for many years carried on the investigation and exploitation of these deposits. Extensive prospecting work was undertaken in the valley of the river Saphet-Darya in the year 1896. The mountain stream Saphet-Darya runs for about 15 to 18 versts,* falling into the river Yak-Su. Its source is in the upper hills, Chazret and Pa. In the upper reach of the Saphet-Darya a narrow, deep gorge is formed which is made up of conglomerates, and these conglomerates are proved to be auriferous. The conglomerates of Saphet-Darya are exceedingly solid and deep, measuring several hundred sagenes. They weather easily and they form gold alluvium which is deposited in the valley. The gold is found exclusively in the form of flakes (flaky gold) which sometimes amount to 50 dolya and even one zolotnik per 100 poods of earth, and flakes of 10 to 12 dolya are to be found with considerable frequency. Allotments in the valley of the Saphet-Darya to Russian subjects, Zhoravko-Tokorsky, N. I. Borovsky, and P. I. Reinhard, have been made, of gold-bearing ground measuring 350,000 to 500,000 sagenes each, to which they have obtained full title until such time as the allotments shall have been completely worked out, or may be recognized by the owners as not worth working at all.

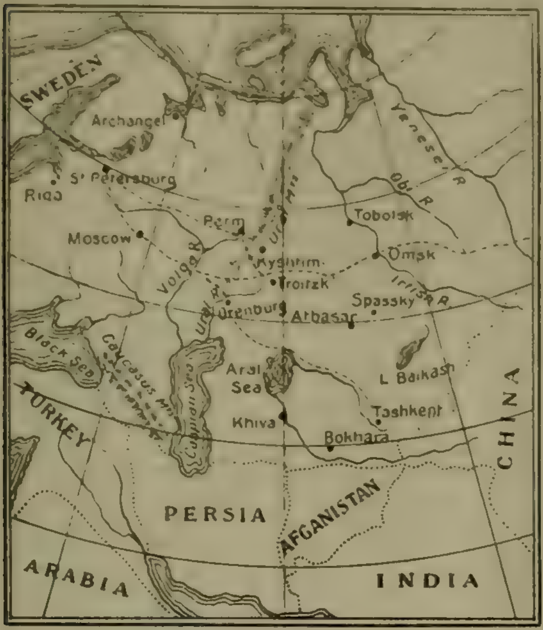
Seeing that the gold deposits are found within the limits of the Khanate of Bokhara, the producers have found it convenient to enter into an agreement with the Bokhara Government respecting the method of exploiting the allotments made over to them. All the gold produced is delivered to the Bokhara Government in the person of the Beka (Governor), who pays to the producer 5 roubles 25 copecks ($2.78) for each zolotnik of pure gold so delivered. In the form of dues the Bokhara Government retains 5% of

---

*1 verst = 3500 feet.
1 sagene = 7 feet.
1 pood = 36.11 pounds.
1 zolotnik = 0.137 oz. Troy.
1 dolya = 0.00143 oz. Troy.
1 rouble = $0.515.
1 dessiatine = 2400 sq. sagenes.

the gross production of gold, and, besides this, charges two roubles per dessiatine per annum as rental of the allotment. On delivering the gold to the Government the latter pays the producer about two-thirds the value of the gold in money. The receipt of the Government for the gold is handed by the producer to the Russian political agent in Bokhara, through whom the Bokhara Government effects a final settlement of the account with the producer.

Prospecting work and exploitation of gold deposits in the valley of the Saphet-Darya have shown that the auriferous ground begins at the surface, but that the gold content is there rather poor: about two-fifths dolya of gold per 100 poods of sand. At first the bed shows sulphides and pebbles to the depth of about 7 ft. Then there is a stratum about 2 to 2½ sagenes (14 to 17 ft.) of clayey red sand. Below this stratum there is water. Beyond the reddish sand there is a stratum of black sand of variable thickness. The black sand has a very fair content of gold. Beneath this again there is a red sand, mixed with clay. Both these beds are about 14 to 17 ft. thick, and the content of gold in them amounts to 24 dolya per 100 poods in the upper layers, and in the lower about one zolotnik per 100 poods of sand. The succeeding bed, of about 21 ft. thick, is clay and pebble, and contains 7 to 8 dolya of gold per 100 poods of pebbles, and covers a bed of sand which is very rich in gold, making not less than 6 zolotniks per 100 poods of sand. Their rich content of gold, however, is not easily worked because of the strong flow of water. The water can easily be removed by digging trenches in the lower part of the river's route, but this work has not yet been done for want of money. In the year 1910 Mr. Zhoravko-Tokorsky went to Tashkent for the purpose, among other things, of getting money to carry on the work of leading away the water from the gold deposits.



MAP OF WESTERN SIBERIA.

From all that has been shown, it is clearly established that the gold industry in the valleys of the Saphet-Darya and Yak-Su is being industriously developed, and will yield a substantial revenue both to the Khanate of Bokhara and to Russia, the suzerain power.

THE MINERAL DEPOSITS of the Bear River range, Idaho, have been known and prospected for 15 to 20 years and the prospect pits are numerous. The lead ores consist of galena with small amounts of cerussite and wulfenite in a gangue of iron-stained calcite and dolomite, and are found at Swan creek, Utah, and near St. Charles and Paris, Idaho. The copper ores consist mainly of the carbonates, azurite and malachite, in quartz veins. Shipments of ore have been made from two localities, and comprised somewhat less than 100 tons of part lead and part copper ore and about 500 tons of high grade concentrate.

June Copper Production

The output of the Lake Superior copper mines for June is estimated at 19,529,000 lb. fine copper, which is 629,883 lb. less than in the previous month and 652,272 lb. larger than in June 1910. Production by months since January 1 compares as follows:

	1911.	1910.
January	17,614,385	19,200,127
February	17,084,911	18,558,345
March	19,674,764	20,062,442
April	18,359,157	19,473,479
May	20,158,883	19,077,536
June	19,529,000	18,876,728

The May output was the largest since November 1910, due principally to the increase in the output of the Calumet & Hecla properties. The detailed figures for June are as follows:

	June Output (lb.).	Daily Tons Crushed.	Lb. Copper per ton.	Copper, %.
Calumet	6,472,649	9,000	28.5	1.425
Champion	1,597,400	2,400	25.6	1.280
Wolverine	862,000	1,300	25.5	1.275
Ahmeek	1,560,455	2,000	25.0	1.250
Baltic	1,542,800	2,500	24.0	1.200
Superior	310,991	600	21.0	1.050
Allouez	379,780	800	20.0	1.000
Hancock	116,641	230	19.5	0.975
Trimountain	608,000	1,200	19.5	0.975
Tamarack	509,335	1,400	18.5	0.925
Isle Royale	543,159	1,100	18.5	0.925
Mass	129,500	280	18.5	0.925
Osceola	1,605,020	3,800	16.0	0.800
Mohawk	1,080,000	2,600	16.0	0.800
Quincy	1,833,200	4,500	15.5	0.775
Centennial	128,005	300	13.5	0.675
Franklin	103,600	300	13.3	0.665
Victoria	140,000	500	11.2	0.560

Wolverine, which in May had 29.3 lb. copper per ton of ore, fell back into third place in June with a return of 25.5 lb. The June production of the Utah Copper Co. was 7,908,685 lb., compared with 8,360,000 in June 1910. The output last month represents a reduction of 954,215 lb., compared with the record output of 8,862,900 lb. last May. The production compares as follows:

	1911.	1910.
January	6,707,116	4,745,066
February	7,329,326	5,798,819
March	7,260,267	8,100,000
April	8,169,248	7,902,643
May	8,391,870	8,862,900
June	7,908,685	8,360,000
Total	45,766,512	43,869,428

The June production of the Nevada Consolidated was 5,307,400 lb. The comparative production by months is as follows:

	1911.	1910.
January	5,268,954	3,074,458
February	4,992,533	5,115,823
March	5,932,259	5,339,466
April	5,298,632	5,822,351
May	5,277,355	5,500,000
June	5,307,400	6,100,000
Total	32,077,133	30,951,998

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Overvaluation of Prospects

The Editor:

Sir—Your editorial, 'Selling Prospects,' of July 8 is comprehensive and to the point. My business is that of bonding, developing, buying, and selling prospects and mines; it brings me into close contact with the prospector, and his ignorance in estimating the value of his holdings and the price he asks, out of all proportion to the showing made, is a serious obstacle in the making of new mines. An undeveloped prospect is not a mine; it is not even a probable mine; it can only be a possible mine. A mine is a property that has its orebodies exposed underground in such wise that the different blocks of ore can be examined and sampled on more than two sides at stated distances, and the ore must be of a quality and quantity to pay a fair profit over all expenses, including purchase price, taxes, and interest on the money invested for a term of several years. A probable mine is a partly developed prospect that has the orebodies exposed at least on two sides at a depth of approximately 100 ft. below the surface, and the ore must be of a grade to pay all expenses of mining and treatment and leave a fair profit. A possible mine is what the majority of prospectors have to sell, and which they style a mine. It consists of one or more 10 to 20-ft. holes in the ground, and sometimes a location notice, while the ore in most instances is composed of the common sulphide, optimism in big chunks. I have found that a large number of prospectors have no confidence in their claims and will not develop them even when in a position to do so. The best men to do business with are those that have prospected widely, have read up on economic geology, know what constitutes a mine, and realize that the day of the sucker is past. Large investors do not buy undeveloped properties, and as a great many prospectors can not open up their claims sufficiently to interest capital, the need for an intermediate or middle man is created. He is either a mining man himself and does his own selecting; or else a man that knows little about mining, but engages an engineer who is competent and makes a specialty of such work. Having found the right property, he bonds for a reasonable figure without cash payment, develops the property, and, if the showing warrants it, pays the purchase price when the bond expires. Conversely, if results are bad, the bondee is out the money expended, while the prospector, without cost to himself, learned a good deal about his property, a knowledge which is very seldom desired, however. This is one of the safest and most rapid ways of making honest money in mining, provided the man employed in making the selection is capable. The price paid for a good prospect is so much less than that paid for a mine, that one can afford to lose once, or even twice, if the third attempt is a winner. The amount of ore yet to be extracted is much greater in case of a prospect than in that of a partly worked out mine. While the prospect has parted with none of its ore, its capabilities are all held in reserve and its whole life is still before it. The reason the prospector experiences difficulties in selling is not that he has no market for his wares if they have genuine merit, not that investors are shy of risking their money, as witness the number of mining men in the field searching for good properties, but because of his demand to be paid a fortune for some orebody that he claims is somewhere in the ground, but which, in nine cases out of ten, is situated in his imagination. Much has been written on sampling and how the eye unconsciously directs the hand to pick the best ore, but it remained for a chance acquaintance of mine to solve this puzzling problem. He told me, in all seriousness, that he simply shuts both eyes and grabs samples right and left from his dump. How he would manage to sample with a bandage over his eyes, deponent sayeth not.

R. L. Mann.

Cazadero, California, July 18.

Errors in Mine Sampling

The Editor:

Sir—There are numerous factors which tend to cause error in sampling the ore in a mine, most of them of a physical character, though some may be charged to what may be termed the personal equation. This latter is more likely to become an important factor where the person doing the sampling is familiar with the ore. That is, where the sampler is able to distinguish between rich and low-grade ore by its appearance. He may not intentionally take other than what he considers to be a representative sample, but if he be sampling for the owner he is likely to favor the richer ore, whereas, if he represent a possible purchaser, he is as likely to get a full share of the poorer ore, in order not to 'salt himself.' In each case he almost inadvertently introduces a factor of safety, which is perhaps intended for self-protection, as much as for anything else. If the ore is of fairly uniform grade across the entire width of the vein, and the walls are rather soft and likely to break away liberally when stoping is in progress, the sampler usually takes due cognizance of this important fact, and, with a liberality equaling that of nature itself, he includes all the wall-rock in the sample that the situation appears to demand, in order to be on the safe side, or, on the other hand, he as carefully avoids it, if representing the seller, arguing that a careful miner would eliminate the waste as far as possible when mining this ore. This is merely a human weakness, and in most cases is done with no intent to deceive. The influence of physical conditions is often of far greater importance. In some mines the ore is rather loose and crumbling, its principal value being found in the softer portions of the vein. Blows from the pick, hammer, or 'jigger' shake the ground adjacent to the channel as it is cut, and this soft material is jarred loose, falling upon the canvas, thus enriching the sample. In such cases greater accuracy is secured by taking large samples. If the vein be very hard and the valuable mineral occurs mostly in seams or in isolated bunches, then samples that are fairly representative can only be secured by taking very large quantities, and it may be necessary to blast in order to get the desired result. Such veins are by no means uncommon, but the taking of samples in veins where the minerals are 'spotty' requires considerable judgment. The object to be attained is a sample exactly representative of the ore as it occurs in the mine. The most accurate samples can be taken where the rock is rather soft, but not too soft, and where the sampler can cut a channel of uniform section, cutting only that which he wishes to take. But such ideal conditions for sampling seldom obtain.

In some cases the only safe method of ascertaining the value of a vein is by actually stoping and milling the ore, or sending it to a smelter, as no hand samples taken can be depended upon to give accurate results, or to even approach them unless the quantity taken in each sample be so large that it cannot be satisfactorily manipulated on a good sized canvas by two men. I have known of instances where samples were taken in such large quantity that they had to be divided into two or more portions to be worked down separately, finally mixing the several 'quarters' and calling the result one sample. This is all right if the cutting down be carefully done, but if one portion is cut, say three times, and another portion is cut four times, before the several 'quarters' are mixed, the sample is worthless, as then the ratio of one portion to the others is destroyed. Sampling ore is a purely mechanical performance, but it requires great care nevertheless, for the sources of error are many, aside from possible salting, and the sampler must use good judgment and proceed methodically to secure reliable results.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

TO SOFTEN SMALL FILES cover them with oil and hold them over a fire until the oil blazes. As soon as the flame runs all over the file, plunge it into water.

A GLUE that will resist moisture is made of 1 lb. of glue, melted in 2 qt. of skimmed milk. The addition of powdered chalk to common glue makes it much stronger.

TO THAW out frozen water pipes pack them with unslaked lime and wrap up in old rags or carpet. Pour water over the portions thus covered and the heat generated will melt the ice in the pipes.

BAUXITE has but little market on the Pacific Coast as yet, as there are no companies engaged in the production of aluminum in any of the Western States. A small local market for bauxite for other uses is slowly developing.

IRON may be securely cemented to marble by the use of the following preparation: Plaster of paris, 30 parts; iron filings, 10 parts, sal ammoniac, 1 part; mix to a fluid state with vinegar and use immediately, as it hardens rapidly.

A BLACK INK for rubber stamps is composed of nigrosine 3 parts, water 15 parts, alcohol 15 parts, glycerine 70 parts. Dissolve the nigrosine in the alcohol, add the glycerine previously mixed with water, and rub well together.

PLATINUM has frequently been found in association with nickel-bearing copper ores, occurring in ultrabasic rocks; pyroxenites and peridotites, for example. But there is no other reason to expect that actinolite would be likely to carry platinum.

A FORMULA for making white metal for motor bearings, which has given excellent results on heavy high-speed service, consists of 48 lb. of tin, 4 lb. of copper, and 1 lb. of antimony. The copper and tin are melted first, and then the antimony is added.

TO CUT THIN BRASS, first draw a line with a quill pen dipped in a strong alcoholic solution of corrosive sublimate. Let it dry, and then go over the line with the pen dipped in nitric acid, when the metal may be broken like glass cut with a diamond.

KAOLIN DEPOSITS should be located as placers, as they are usually worked by open-cuts and the larger claim gives the necessary room. It would be difficult to identify the 'apex' of a kaolin deposit in most cases, and it is therefore customary to locate such deposits as placers.

ROSIN may be prepared for soldering bright tin by the following method. Take 1½ lb. olive oil, 1½ lb. tallow, and 12 oz. pulverized rosin. Mix these ingredients and let them boil up. When cool, add 1⅜ pt. water saturated with pulverized sal ammoniac, stirring constantly.

CHISELS may be tempered by using the following formula: To 3 gal. water add 3 oz. nitric acid, 3 oz. sal volatile, 3 oz. sal ammoniac, 3 oz. alum, 6 oz. salt, with a double handful of hoof pairings. Heat the tool to a cherry red. This has put new life in steel that has apparently been burned, and is used to temper chisels for cutting French buhrstones.

NITRE can be extracted from nitre-bearing earth, on a small scale, by simply leaching the earth with water and evaporating the resulting solution, taking care to first filter or clarify it. The resulting product would be somewhat impure, but would find a ready market among manufacturers of chemicals, who would purify it.

HARDENING an ordinary drill in sulphuric acid makes an edge that will cut tempered steel or facilitate cutting hard rock. The acid should be poured into a flat bottomed vessel to a depth of about ⅛ of an inch. The point of the drill is heated to a dull cherry red, and dipped in the acid to that depth. This makes the point extremely hard, while the rest remains soft. If the point breaks, reharden, but with a little less acid in the vessel. After hardening a drill in this manner, wipe off the acid, if any remains on the point of the drill, before it attacks the metal and destroys the cutting edge.

ASBESTOS is all of secondary origin, and may be derived by alteration from various rocks, generally rich in olivine or pyroxene. Some of it, however, is derived from impure limestone. Rocks originally rich in olivine are by far the most important source. They alter to serpentine, and under favorable conditions give rise to asbestos. The purer the serpentine the more likely it is to contain asbestos, especially if the serpentine has been greatly fractured and intruded by granitic dikes, as in the vicinity of Thetford, Canada. Rocks and conditions similar to those of the asbestos region of Canada, but much less rich in asbestos, occur near Lowell, Vermont, and Casper, Wyoming, where prospecting and mining operations are now being carried on.

TO protect wood from decay the tissue must be protected from the invasion of the spores of the fungi which give rise to decay, or it must be so altered by chemical change that it will no longer be a suitable medium for their growth. Certain chemicals have the property of protecting wood from decay, but the trouble is to bring them into sufficient contact with the cellular tissue of the wood and then to make the contact a permanent one. To this end the substance used must not evaporate at ordinary temperature nor be soluble in water, hence aqueous solutions of antiseptic chemicals will not avail when the treated wood cannot be protected from moisture; neither will the light oils give more than temporary protection, even when combined with the powerful antiseptic coal tar acids, for they evaporate in a short time and the temporary protection ceases. It therefore follows that the heavy oils, insoluble in water, that do not evaporate at ordinary atmospheric temperatures, combined with powerful chemicals, which are both antiseptics and germicides, are the ideal and rational preservatives for wood.

ROOFS of sheds and other structures requiring lightness of construction combined with fire-resisting qualities are often made of a combination of structural steel shapes with a corrugated-iron roof. In this way a roof can be obtained which is made entirely of metal that can be easily removed if occasion should require. It often happens, though, that there is no adequate means of fastening sheets to the iron. If the sheets were riveted directly to the angle irons, the expansion and contraction would tend to make the rivet hole enlarge continually. However, the following type of fastening has been found to work satisfactorily in many cases where corrugated sheets were fastened to iron angles. A piece of strap iron is riveted at one end to the ridge of the corrugation on the under side, and passed under the angle iron, and then again riveted to the ridge of the corrugation at the other end. In this way expansion of the sheet is allowed for, and at the same time there is little or no danger of water passing through the rivet hole. With roofs of this character it is often the practice to make the span between purlins of considerable length, as the corrugations give to the roof a stiffness which will support a fairly heavy weight of snow.

Special Correspondence

JOHANNESBURG, TRANSVAAL

April Gold Production.—South African Coal.—The Middelburg District.—Tin Mines of the Rand.—Messina Copper Field.

The Transvaal output of gold for the month of April, according to the Mines Department, was £2,823,121 in value, as compared with £2,883,332 in March. For a 30-day month this is considered satisfactory, and probably another record gold output will soon be forthcoming. The number of tons milled was only 40 tons short of 2,000,000, and this should be reached when May results are known; at all events, with the additional stamps dropped at Randfontein and the new mill started at Brakpan, that level now must have been exceeded, especially as the Meyer & Charlton mine again enters the list of producers this month. At Johannesburg there is a tendency to compare other mining industries with that of gold, and so it is that we hear of the Transvaal coal-mining industry being fast reduced to a pennyweight basis, the average value of coal at the collieries coming out last month at only 4s. 9d. per ton, and further reductions in the selling price are likely.

Middelburg has become the principal coal-mining district of the Transvaal, and supplies quite three-fourths of the whole coal output of the province, but there are not wanting signs that before long the coal centre of the Transvaal will have to be moved again. The Witbank company and the Cassel company are examining new areas, and, generally speaking, there are few new areas containing coal of standard quality along the Pretoria-Delagoa bay line available for future working. The price at the mine in the Middelburg district was last month 4s. 7d. per ton, but that of the outside districts was even lower, by a penny per ton. The Consolidated Gold Fields of South Africa has opened a large colliery at Breyten, in the eastern Transvaal, some 150 miles away from the Rand, and within twelve months of commencing mining operations is turning out nearly a thousand tons per day. Some commotion has been caused in the local coal trade through this action of the Consolidated Gold Fields, especially as it has led to a revision of the railway rates for the carriage of coal from these outside districts, thus enabling them to compete more effectually with the Middelburg collieries. It is, however, to these more distant fields that the Rand will soon have to look for its future coal supplies, as the untouched coal areas in reserve and within easy reach of the railway in the Middelburg district are somewhat limited. It is anticipated, however, that the changing over from steam to electricity at the gold mines will reduce the coal consumption on the Rand by nearly a third. However disagreeable a fact this may be to the existing collieries, it will be to the permanent advantage of the gold mines and the Rand, for, after all, the coal resources of the Transvaal are not by any means as superabundant as commonly supposed.

The estimated value of the mineral output of the Transvaal during April, excluding gold, diamonds, and coal, was £63,415, an amount apparently small, but, nevertheless, a record output. Of this total, tin ore comprised no less than £48,281, and, as before remarked, the tin-mining industry here is progressing, helped by the prevailing high price of tin and the promising outlook of the northern tin-fields. Had today's discoveries been made six years ago, the tin boom of that time would have established a sound tin-mining industry, but the engineers called in to report upon the discoveries made six years ago overrated their value and importance, with the result that speculators all look askance at the more promising discoveries made today farther north in the Waterburg district. The copper ore exported in April was only valued at £4328, but much better things are confidently looked for in the Messina copper field, once the sanctioned line of railway becomes available for traffic. Already the Messina company has made arrangements to secure more working capital, so that the property can be worked on a much larger scale, and the other companies interested in that field are also making preparations to commence work.

LONDON

New Move at Carn Brea & Tincroft.—Progress in West Africa.—Taquah Ore Reserve.—Abosso Yearly Report.—Additional Equipment.

A notable alteration of policy has recently taken place at the Carn Brea & Tincroft mine in Cornwall. I have often referred in this column to the past and current history of this old tin mine and have shown that it just manages nowadays to jog along, sometimes making a loss and sometimes a small profit. Six months ago R. Arthur Thomas of Dolcoath examined the property and pointed out the fatuous practice of mixing clean tin ore with tin ore containing much wolfram and stamping the whole lot in one battery, instead of treating them separately. He advised them to alter their practice, and to buy a Wetherill magnetic separator for the tin-wolfram ore. Lord Clifden, one of the ground landlords, put up the money for this purpose, and as he is already a large shareholder, he has been able during the last few months to obtain virtual control of the property. On the death of John Penhall, the manager, two months ago, he insisted that the management must be put in the hands of a more experienced man than a local Cornish mine captain, and secured the appointment of Edward S. King as consulting engineer. Mr. King is well known in Australia as a capable and enlightened engineer, and if he is given funds and opportunity he ought to put the mines on quite a different basis. Already he has created a mild sensation by advertising for tenders for supplies, following on the same track as Mr. Battens at the Grenville. This change of policy has made Frank Harvey and J. C. Daubuz sever their connection with the company and resign their directorships. Mr. Harvey came to the rescue of the company twenty years ago when there was a likelihood of the mines being closed, and bought a large number of shares. But he is a merchant and much of the mine supplies were bought through his firm. Mr. King will find some difficulties in his way when fighting for a free market, but if he is backed by the Clifden interests he should come out all right.

News from West Africa usually emanates from London. On the spot nothing is known at first hand of intentions, policy, or results of operations. During the last year or two some of the big mines have suspended mining and milling operations and have done much development work. For instance, two years ago at the Prestea Block A a large amount of additional working capital was provided by Wernher, Beit & Co. and the Consolidated Gold Fields of South Africa, and H. F. Marriott was appointed consulting engineer. It was decided to build a new treatment plant containing 110 stamps; 60 of these have been erected and 40 of them started work at the beginning of May. On December 31 last the ore reserve was figured at 678,859 tons, averaging just over 10 dwt. per ton. The main shaft is down 624 ft. and the Appantoo shaft 724. The company publishes a vertical section showing the ore blocked out, with notes of the tonnage and content. Important recent events have been the completion of the railway to the coast and the absorption of the adjoining Prestea Mines property. The railway had been long delayed owing to the difficulty of building a bridge over the Ancobra river, which is continually subject to floods. The mine has had a good deal of bad luck. For one thing, the supply pump at the Ancobra river broke down, and in the meantime water for the mill has to be obtained from the mine. Then the steel stack fell during erection. The boiler plant was in a forward state, and the steel stack, 140 ft. high by 8 ft. diameter and about 30 tons weight, was being lifted into place when a derrick canted, throwing the whole weight onto one block, which gave way, so that the stack fell right across the boiler-house, and the whole of the middle section collapsed as if made of paper. The roof of the boiler house was badly crushed, but being a steel building it fortunately prevented the stack from falling on the boilers beneath. The repair of the stack will cost hundreds of pounds besides delaying the completion of the boiler plant.

Mining and milling have also been suspended at the Taquah since June 1910. This mine is one of the Oceana Consolidated group, and the company working it also owns a large share in the Abosso company, farther north on the same line of banket deposit. For some years both of these mines were under the management of G. A. Stockfeld. A few months ago Mr. Stockfeld's services were transferred to the West African Trust, a development company belonging to the same group, and J. W. Newbery succeeded him. R. Recknagel and S. R. Adams then examined the mine, re-estimated the ore reserves, and made suggestions for the modification of mining methods and the improvement of the power plant. Two months ago W. R. Feldtmann was appointed consulting engineer. In June 1910 a serious accident occurred in the main shaft, and mining operations had to be suspended. It was decided not to resume mining and milling, but to push ahead with development work. On February 28 last, Mr. Recknagel estimated the ore reserve at 102,370 tons, averaging 78s. 3d. per ton; he rejected 107,370 tons which he considered unprofitable.

The latest information about the Abosso above mentioned is contained in the yearly report for the period ended June 30, 1910. During that time 77,623 tons of ore was sent to the mill, and by amalgamation and cyanidation 41,125 oz. gold was recovered, worth £174,834, or 45s. per ton. The working profit was £51,196, out of which £14,310 has been written off for depreciation and for shaft extensions, and £5894 has been paid in taxes, leaving a net profit of £30,991. The year commenced with a balance of £31,203, and dividends amounting to £60,000 have been distributed during the year, being at the rate of 15%, leaving a balance carried forward of £22,194. An additional 50 stamps are now being erected, as also is an electrical pumping plant at the main shaft. When the latter is at work sinking will be re-commenced. On February 28 Mr. Recknagel estimated the ore reserve at 284,028 tons averaging 47s. 3d. per ton, and 58,210 tons averaging 19s. 9d. per ton.

BUTTE, MONTANA

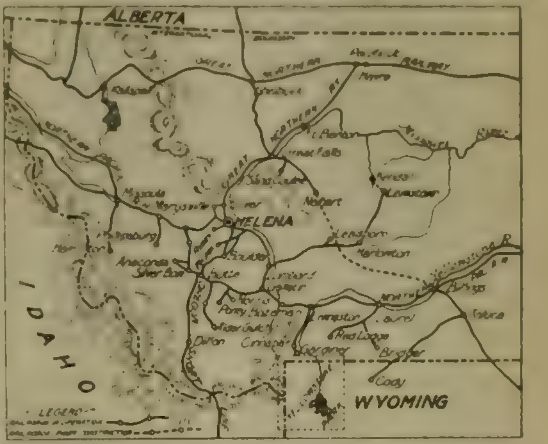
Smelter Fume Commission.—Use of Compressed Air at the Anaconda. — Georgetown District. — Sinking at Pilot Butte.

A commission of experts and scientists, appointed by Attorney General Wickersham to investigate the smelter-fume question at Anaconda, has been at work for a week, but of course the members have given no intimation of their opinions. Of the three members of the commission, one is supposed to represent the 'smoke farmers,' another the Anaconda company, and the third the Government. They will attempt to decide whether or not some system can be installed to prevent the injury complained of by the farmers.

By the first of August the Diamond-Bell mine of the Anaconda company will be operated by compressed-air power. The Mountain View mine has been using the new power with splendid success for two months. As soon as the Diamond-Bell is started the High Ore will be shut down, and the change from steam to compressed air will be made there. Officers of the Anaconda company say the saving on the cost of production using the new power will prove more than had been estimated, and the economy greater than had been guaranteed by the manufacturers who are installing the plant. The Anaconda company has decided not to build a railroad from Anaconda to the Georgetown gold-mining district, claiming that the tonnage in sight is not sufficient to warrant the extension. As the district is almost inaccessible by wagon, the decision of the Anaconda company will practically put an end to development work there at present. Some of the companies organized to operate in the Georgetown district may conclude to build a branch line to connect with the Anaconda road at the town of Anaconda.

The new surface plant of the Tuolumne company has been received from the Nordberg company, and it is expected that the new hoist will be in operation by October 1. The engine weighs 88,000 lb. and has a capacity of 1000 tons in six hours. It is officially stated that the company has no intention of increasing its dividends this year, and not for some time thereafter unless there is a decided improvement in the metal market. Very little work is now being done in the property of the Davis-Daly company in Butte. A few men engaged in development work in the Colorado mine comprise the extent of operations.

The Pilot Butte Mining Co. has pumped the water from the shaft and has resumed sinking. The cross-cut from the Blackrock mine on the 1600-ft. level has been extended 150 ft., and 410 ft. more will take the cross-cut to a point under the Pilot shaft. Raising and sinking will be carried on at the same time. The old Gagnon mine hoist and surface plant are being torn down, the old shaft having been abandoned as a working shaft. The mine has been connected with the Original mine of the Anaconda company and the Gagnon is now being mined through that property. The new Gagnon shaft has reached a depth of 1750 ft.; when completed down to the 2300-ft. level and connected it will be used to work a portion of the property.



MAP OF MONTANA.

NEW YORK

The Copper Market.—Production of Utah Copper.—Giroux Shipments. — Sale of Gill Holdings. — Tharsis Copper. — Kerr Lake Dividend. — Cobalt Central.—Porcupine Fire.—Shut-down of A. S. & R. Plants.

The report of the Copper Producers' Association covering the month of June was made public July 8, and the expected and much-talked-of decline in surplus stock was made apparent. The decrease in surplus was 8,561,768 lb. June production was 124,554,232 lb., which is well up toward the high mark for the short months, being just about the full per diem output. It is not to be wondered at that the market has failed to show any signs of stimulation. It is impossible to compare the present conditions governing the copper situation with conditions prevailing ten years ago, or even five years ago. The consumers are not overlooking the fact that the porphyries could make money on 10c. copper, if forced to sell at that price.

Some of the important people in the metal market are beginning to scold the public for its present attitude and to insist that attention should be directed to the enormous consumption rather than to the production. A New York metal man, whose position is an important one, states that consumers are refusing to carry stocks on hand. He says in part: "I know of one large consumer who has heretofore carried forty to fifty million pounds of copper in stock, who today has but a few million pounds on hand and who now buys a million pounds at a time."

This illustration is typical of the consumers' stand, and their belief that they can get cheap copper at any time is based on the knowledge that the low-grade milling coppers cannot curtail or limit production, but must continue to make and market their production at whatever profit can be had. An instance of the factors in production which influence the consumer, is the adding of three new shovels by the Utah Copper Co. for stripping on the Boston Consolidated. The recovery of copper at the Utah plants is now said to be higher than the mills have ever made before. From time to time, there has been a great deal of stress laid upon the eventual inevitable needs of the Orient for copper as telephone and telegraph lines, electric light and railway systems spread over the land. Evidently the celestials do not intend to pay all of the tribute to the 'foreigner.' The Chinese Government has sent the Chinese supervisor of mining and smelting operations to Butte to study the Washoe smelter and prepare for the installation of modern mining and smelting methods in China.

The report covering June operations at the Greene Cananea, while showing a considerably smaller output, is still very encouraging. Greene Cananea has dragged and dragged in the market, and the holders of the shares have long been weary. The reconstruction of the Greene Cananea plant has been completed, and the important feature of the present showing is a 9c. cost. If the metal market justifies placing the property on full production, it is now in shape to turn out some 50,000,000 lb. annually. At present it is producing just a little more than 50% of this amount. If a 9c. cost can be maintained, Greene Cananea ought to make, on the present output, with copper at 12½c., about $1 per share, equal to approximately 9% on the present market price of the shares.

It is being said over town that Giroux is soon to begin shipments to the Tooele smelter. A conference is said to have been arranged for a settlement of the freight rate that Giroux will have to pay to the Nevada Northern, and by this means indirectly to the Nevada Consolidated. Giroux has been very much of an enigma for the Eastern shareholders. Whatever the mining problems encountered by the management may have been, a policy of reticence has been maintained and shareholders have been mostly left to surmise. There is a report that native copper has been found on the 1400-ft. level. It seems to be quite the prevailing order of things that plants should be increased in capacity while in course of construction. Nearly all of the large plants erected recently in the low-grade mining camps have been enlarged almost before foundations have been completed. The International S. & R. Co. is following this innovation in adding its lead stack to the plant at Tooele; original plans contemplated the construction of two furnaces, now a third furnace is to be added, and the first two will be blown in probably in October.

The holdings of the late John Gill in the Arizona Copper Co. have been sold. Mr. Gill was chairman of the board of the Arizona for many years and owned some 150,000 shares of stock. One half of this stock was bought by interests connected with the Tharsis Sulphur & Copper Co., Ltd.; the remainder was sold through a Glasgow brokerage house to individual parties for investment. An early report on the Arizona properties is expected from the secretary, Y. J. [illegible], and the company's engineers who visited the property last spring. If the report as to ore reserves and the future outlook is favorable, it is rumored that some £200,000 will be raised by debenture issues, and the funds expended in the erection of a modern plant which will include all of the latest improvements in handling and reducing ores. The Tharsis company, which now is more closely associated with the Arizona, is one of the oldest copper producers in the world and operates the [illegible] in Huelva, Spain. The Scotch management has retained the primitive methods of ore treatment. The ore is piled in heaps and sprinkled, weathering and leaching follows, the leach-water going into timber sluices and the copper in solution being deposited on pig iron. The management has paid dividends of nearly 20% per annum for almost half a century, a dividend record hardly equalled by any other copper mine in the world.

Kerr Lake is one of the first big dividend payers in Cobalt to reduce its dividend rate. The company has been paying 50c. quarterly, the same as Goldfield Consolidated and Amalgamated Copper. The declaration for the current quarter, however, reduces the disbursement to 40c. There has been very little litigation in Cobalt concerning ownership of orebodies, as Canadian mining laws are not obstructed by any obnoxious apex theory, but the Kerr Lake company has been made defendant in a suit by the Hargraves Silver Mines, Ltd., claiming $150,000 for ore wrongfully taken from the Hargraves ground adjoining the Kerr Lake. Kerr Lake makes silver at a cost of about 13c. per ounce and has been earning little more than its dividend for the past eighteen months or so. An important innovation made by this company is the recent installation of three jigs to handle low grade ores of 50 oz. per ton, or better, the concentrate from the jigs to go to the Nova Scotia mill.

A syndicate of Philadelphia holders of Cobalt Central has made the first deposit with the liquidator on the purchase price of the Standard Cobalt properties. The Standard properties were controlled through stock ownership by the Cobalt Central Mines Co. There are some other claims belonging to the Cobalt Central, but present plans are apparently hazy as to whether the Pennsylvania holders are to form a new organization, or endeavor to rehabilitate the Cobalt Central. The shareholders in the old company have been bombarded and importuned for a contribution by various committees and factions until they have mostly lost interest in such plans. At present both the new syndicate and a faction in the old company are making separate appeals.

The previous fires which have visited Porcupine, while disastrous enough, have been dwarfed by that which swept through the forest and devoured the camp this week. An area of some two miles in width and twenty-five miles in length was swept by the flames with a terrific loss of life and property. The Dome and the properties immediately adjoining suffered most heavily. The townsite of South Porcupine was directly in the path of the flames, and the people were forced to take refuge in the lake, where many were suffocated or partly suffocated, and drowned. Pottsville and Golden City were also burned. Best estimates at present give the loss of lives at 200, mostly foreigners, many of whom were so little known as to make identification impossible. Many miners and workers at the various camps in the forest took refuge in the shallow shafts which have been sunk and were later found dead from suffocation. The disaster, undoubtedly bound to come sooner or later, will retard progress for the coming summer. The loss of life is terrible. So far as the physical effect on the camp is concerned, it will not be wholly detrimental. The burned-over part of the camp will have no bush fires next summer and a great deal of exploration work will be made easier. There was a severe break in the New York market in Porcupine issues, but trading was restricted owing to the action of the Toronto Exchange in closing for the day.

The shutting down of the plants of the American Smelting & Refining Co. at Chihuahua and Aguascalientes has been a matter of some discussion, but it is authoritatively announced that such action is due altogether to unsettled labor conditions, and mines and smelters are alike waiting for the prevailing unrest to wear itself out. It is reported that [illegible] men have struck at the Chihuahua smelter, and that at Mapimi, in Durango, 400 men have struck demanding an increase in the rate of pay. At Velardeña men now receiving $1.25 are demanding $2 per day.

MEXICO

The Potrero Gusher—Large Daily Flow—Tampico Pipe-Line—Long-Term Contract—Oil Resources of Mexico.

For the first time since it was brought under control, several months ago, the mammoth gusher of the Pearson oil interests, in the Potrero de Llano field, State of Veracruz, Mexico, was recently allowed to perform for twenty minutes for officials of the Texas Oil Co. and the Gulf Refining Co. It required the efforts of three men to open the gate valve, and a column of oil shot into the air to a height of 400 ft. The flow was estimated at 100,000 bbl. daily. The party that witnessed the performance of the gusher was composed of J. R. Sharp, J. C. McCue, J. C. Daring, and S. Bates, of the Texas Oil Co.; J. F. Fisher, E. T. Gatterell, and J. H. Tucker, of the Gulf Refining Co., and Thomas J. Ryder, general manager for the Mexican Eagle Oil Co., the marketing concern of the Pearson interests. The American oil men have been examining the Pearson holdings, and it is announced that plans are being made for the erection of storage at some point in Veracruz, and the purchase of crude oil from the Pearson and other wells for American markets. The probable purchase of the Pearson properties has been rumored, and it is admitted that the examination may have such a result.

With the possible exception of the Dos Bocas gusher, also brought in by the Pearson interests in the State of Veracruz, and which burned out, the Potrero gusher is the greatest in the history of the oil industry. The big Midway gusher ranks as an infant in comparison. The well came in on December 26 last, and before it was brought under control the flow was estimated as high as 170,000 bbl. daily. The gusher flooded the surrounding country and sent an enormous quantity of oil down the Tuxpan river into the Gulf of Mexico. People living in that section of Veracruz protested to President Diaz, declaring that lands were being ruined, waterways rendered unfit for navigation and the watering of cattle, and properties threatened with destruction by fire. In reply to the protest, Lord Cowdray, head of the Pearson interests, stated that payment would be made for all losses sustained, and later this was done.

Bringing the gusher under control was a herculean task, and weeks were consumed in accomplishing it. With the object of saving the production, earth storage was hurriedly provided, and subsequently the stream of oil was directed into the reservoir. Finally, after repeated efforts, the monster was brought under control, and the flow shut off. The valve holding the gusher has a strength of 2400 lb. to the square inch, and the pressure of the well is estimated at less than 1000 lb. per square inch. The oil in the Potrero reservoir is estimated at 3,000,000 bbl. The petroleum lake is fully a mile around, and at places the oil is 30 ft. deep. This was the fourth well drilled by the Pearson interests in the Potrero field. In all, six wells have been brought in there. No. 1 and 2 are intermittent gushers.

MEXICO.

Two stretches of 6-in. pipe-line have been built to give the Potrero field connection with the Gulf port of Tampico. One links the field with the Tamiahua lagoon, and the other extends from the lagoon to Tampico. Barges carry the oil between the pipe-line stations on the lagoon. The present pipe-lines are to be connected by the building of another link, and the construction of an 8-in. pipe-line from the field to the Gulf port of Tuxpan has been ordered. At Tuxpan the Pearsons have storage for oil from the Furbero field of the Oil Fields of Mexico company, a long-term contract covering the Furbero production up to 12,000 bbl. daily. Under this contract the Pearsons built a pipe-line and railroad from the field to Tuxpan. Oil is shipped in tank steamers from Tuxpan to the Minititlan refinery of the Pearson interests, on the Tehuantepec isthmus.

POTRERO GUSHER.

The Potrero gusher, and the success of the Huasteca Petroleum Co. in the Juan Casiano field of Veracruz, have turned the attention of oil men to Mexico's possibilities. The Huasteca is a subsidiary of the Mexican Petroleum Co., Ltd., of which Edward L. Doheny, of Los Angeles, is the head, and it recently made the first shipment of Mexican crude oil to the United States, the Standard tank steamer *Captain Lucas* carrying 32,000 bbl. to Sabine Pass, Texas. The Doheny concern has two gushers and several flowing wells in the Juan Casiano fields, and has an 8-in. pipe-line from the field to Tampico. Materials for a second pipe-line have been ordered. Huasteca oil is being delivered to the Waters-Pierce refinery at Tampico and to the plant of the Mexican National Gas Co., another Doheny concern, in Mexico City. Also, it is being mixed with oil from the Ebano wells of the Mexican Petroleum Co. of California, another subsidiary of the Mexican Petroleum Co., Ltd., for delivery to the National Railways of Mexico for use in the locomotives of the merger system. According to a recent report, the Huasteca has entered into a contract to supply 6,000,000 bbl. of fuel oil for use by the Southern Pacific interests on their Texas lines. The Southern Pacific has long been using fuel oil from California on its lines.

General Mining News

ALASKA

Fairbanks District

It has been estimated that the placer mines tributary to Fairbanks will output not less than $5,000,000 for the season 1910-11, and may reach $6,000,000 if the quartz mines be included. The Chena custom mill is running steadily in the southern outskirts of Fairbanks. The results obtained in the operation of this mill are said to have greatly stimulated confidence in quartz mining in the district. The mines of the district are prepared to supply all the ore the Chena mill can crush, and it is expected some of the companies will build mills this year.

A story comes from Goodnews bay, a short distance south of the mouth of the Kuskokwim river, to the effect that rich beach diggings have been discovered at Goodnews, similar to those at Nome. There have been several disappointments in that vicinity in the past, and details of this alleged new discovery are very meagre.

It has been announced at Dawson that hereafter all gold that is the output of quartz mines in Yukon Territory will be exempt from the payment of the royalty that is assessed against the product of the placer mines, and may be taken out of the Territory free of tax. The order abolishing the duty came from Ottawa and is official. The purpose of the order is to encourage the mining of quartz in the Yukon, and as an incentive to all activities connected with the industry. The remission amounts to 2.5%, the tax collected hitherto in the form of an export tax upon all gold dust and bullion when it crossed the border.

PLACER MINING NEAR FAIRBANKS, ALASKA.

Prospecting is being industriously followed on American creek, Hot Springs district, in the Fairbanks region. Some of the miners are said to have found very good pay gravel. One Fairbanks miner is said to have 4 ft. of dirt that washes 4 cents to the pan. Discoveries have also been made on Colorado creek, a tributary of the American.

A discovery of galena is announced as having been made by J. P. Nirich in a vein on Twin creek. It is reported the ore is worth over $100 per ton in lead, silver, and gold. Ninety tons of ore from Bedrock creek, near Fairbanks, which was milled returned $110 per ton.

ARIZONA

A despatch from Phoenix states that the value of the output of the mines of Arizona for 1910 was $42,229,282, which was $717,462 less than for the preceding year. There was a notable increase in gold and zinc, but decreases in copper, lead, silver, iron, and sulphur. The figures are the sworn returns to the auditor of the Territory, just compiled, being the basis of mine taxation for the current year.

Cochise County

For the six months ended June 30 last, there was shipped from Courtland, by the Great Western Copper Co., 191 cars of ore. This company is employing 75 men in and about its mines.

Graham County

The property of the Frisco Placer Mining Co. is 7 miles from Morenci, where there is from 3 to 12 ft. of gravel said to contain 50 cents per yard in gold. A plant of 250 yards daily capacity has been installed. The gravel is brought to the bins above the plant by means of cables, to which is attached a large plow and a number of scrapers, the plow loosening the material, the scrapers picking it up and bringing it in. Many Mexicans will be necessary here because of the boulders, but the ground will be moved rapidly. There is so much iron in this material it clogs the sluices. A jig has been put in to handle the material coming from the trommels, which takes out this iron, and the sand passes down into and through the sluices. It is a wet plant beginning with the first trommel. About 500 gal. of water per minute is necessary, this being supplied by a centrifugal pump, operated by a gasoline engine, which also furnishes motive power for the entire plant.

Mohave County

The Gold Road mine shipped $34,000 in 8 days recently. The mill is treating 300 tons of ore daily. S. R. Porter has bought the Lealand mines, in San Francisco district. The mill, which is 11 miles from the mines, is to be removed to the property and a water-supply provided. It is reported that a company has been organized to furnish a water-supply to the Tom Reed and other mines of that vicinity. The water is to be pumped from shafts to be sunk near Spears lake. The Minnesota-Connors mine, at Chloride, is again in operation and development will proceed in the mine, instead of on the old dumps as heretofore.

Pima County

It is reported that the Guggenheims are investigating the extensive mining properties of the Tombstone Con. Mines Co. at Tombstone. This report further says that they will also purchase from the Development Company of America, which is the parent corporation of the Tombstone Consolidated Mines Co., all of its other properties in Arizona, including the Imperial Copper Co., the Imperial Mines Co., the Saddle Mountain Mining Co., and the Christmas mines in northern Arizona.

According to report, Tucson is to have a smelter, to be built by the Pioneer Smelting & Refining Co. The site for this new enterprise is near Twin Buttes and is 18 miles from Tucson. Work has been commenced and materials are being taken to the smelter site as rapidly as possible. It is hoped to have everything in readiness to blow-in in December. There are several mines in the vicinity of the smelter, including the Twin Buttes and Helvetia.

CALIFORNIA

Amador County

(Special Correspondence.)—The South Eureka Mining Co. has commenced the unwatering of the Oneida mine, adjoining the South Eureka on the south. It is understood that the South Eureka people have decided to install a new milling plant, provided developments in the Oneida prove satisfactory. It is said that the South Eureka company paid $100,000 for the Oneida group. At the Central Eureka the mill is running on good ore from below the 1200-ft. level, and it is said the June clean-up netted the company $7000. Grading for machinery is under way at the South Amador. A shipment of electrical equipment is expected to arrive shortly. This property embraces the Amador Queen, Doyle, and other claims, comprising a total area of 100 acres a short distance south of Jackson. J. McSorley is superintendent. The South Jackson Gold Mining Co. has commenced sinking a 3-compartment shaft, using a windlass until the recently ordered hoist arrives. It is planned to sink the shaft to a depth of 1000 ft. The property embraces three claims. The Bay State mine, four miles from Plymouth, was purchased recently by A. Levinsky of Stockton, understood to be representing the creditors, for $40,000. The property was sold at public auction to satisfy judgments held by the Stockton Savings Bank, B. Levaggi, and others.

Jackson, July 15.

Butte County

(Special Correspondence.) The Triumph Gold Mining Co. at Lumpkin, one of the large producing mines in the earlier days, has been taken over by M. B. Sears and associates of San Jose. Mining is advanced by means of two tunnels, which run in on a large blanket vein of quartz and gouge. A two-stamp Hendy mill has been running to test the ore during development, which has been found to be a free-milling ore with no complications. A new Beers 6 ft. Chilean mill has been ordered from Sacramento, to be placed within the next 60 days, so that the capacity may be increased to 20 tons per day. Stoping and handling the entire ore supply from the tunnel will be one of the big items of economical operation in conjunction with the use of cheap water power. J. R. Sears is superintendent.

Lumpkin, July 11.

Calaveras County

Twenty more stamps in the 60-stamp mill of the Lightner Gold M. Co. at Angels have been put in operation, making a total of 40 now dropping. The remaining 20 will be put in use in the near future.

It is reported at San Andreas that the Easy Bird mine, which has been idle for some time, is to resume operations. A shaft will be sunk. The mine is equipped with a mill.

Kern County

Lakeview No. 2 went into the sand at 2630 ft. at 1:30 o'clock on the afternoon of the 11th inst., and for an hour sent out a big stream of oil and gas, roaring like the old one and attracting the attention of everyone on the field. It sanded up, leaving 700 bbl. of oil in the sump. Bailing was started in a short time, but up to this time the flow has not resumed. The well is in the southwest corner of the southwest quarter of section 34, 32-24, about 2000 ft. northeast from No. 1, and is 400 ft. deeper than the gusher.

The average recovery for 12 tons of ore cleaned up at the Red Dog mill from the Santa Ana mine was $53 per ton. The ore was mined from the Sanderson shaft. The La Crosse Mining Co. has resumed operations and men have been put to work by Ed. Higgins, the superintendent. The company has taken options on the Santa Ana mine and the Stanford Mining & Reduction Co.'s plant at Johannesburg. Burke and Buys have extracted several tons of good ore from the Wedge mine. The best rock was taken from the 100-ft. level.

The Butte mine is shipping steadily to the Red Dog mill. Jesse Jewitt and William Atkinson are stoping rich ore on the 300-ft. level of the Pearl Wedge. Operations are being carried on with the aid of machine-drills.

The recently discovered orebody on the Miller and Watchman lease of the King Solomon is developing. The east drift is in 25 ft., showing 18 in. of ore in places.

The new shaft on the Twin Brothers claim of the Consolidated Mines Co. is down 60 ft. The ore at this depth, while good, is not of sufficiently high grade to warrant shipping to the mill.

Mariposa County

A 20-stamp mill is nearing completion on the Oro Rico mine at Penon Blanco, 3 miles north of Coulterville. The Hasloe mine, 7 miles east of Coulterville, is idle and the machinery is being removed. The mine has been operated for some time past by a company of which H. P. Dalton, assessor of Alameda county, was the recognized head. Work on the Bondurant mine, near the Hasloe, continues without interruption. This is one of the oldest mines of the district, and has been worked at intervals for many years.

The Heaston mine at Jerseydale, 10 miles east of Mariposa, is working 15 men. The mill has been running about a month.

Mono County

The Hess mine, 15 miles north of Adin, is in operation, with a 10-stamp mill running. This is a new enterprise and is reported to be making a success.

Nevada County

(Special Correspondence.) J. M. O'Brien last week closed the deal for the Champion mines at Nevada City. The first payment was made and he immediately put the North Star Mines Co. into full and exclusive possession of the property. The assistant superintendent of the North Star was in San Francisco on Monday to purchase new equipment for the property. This group consists of about 45 claims with a record of $25,000,000 production. Mr. O'Brien is now operating the Tightner mine, at Alleghany, in Sierra county.

Nevada City, July 15.

(Special Correspondence.) The estimated production of the Grass Valley mining district for the first half of 1911 is placed at $1,000,000. Of this the North Star produced about $510,000, and the Empire $400,000. The other chief producers were the Pennsylvania and Sultana groups. The unwatering of the shaft at the Holbrook drift mine, at Deadman's Flat, is progressing rapidly. The 70-ft. shaft will be sunk 35 ft. deeper to strike the bedrock, near which the ancient gravel channel is expected to be intersected. A gasoline hoist and Cornish pump were recently placed in position. The North Star Mines Co., which, though J. M. O'Brien, bought the Champion mines at Nevada City, will drive a drift from the 1000-ft. level, with four or five more at various other stations. The contract for a stamp-mill has been let to the Martin Foundry of Nevada City, but it is said that no attempt will be made to operate the mill until a large quantity of ore has been developed. A. D. Foote, general manager for the North Star Mines Co., will have personal charge of the Champion operations, with his son, Arthur B. Foote, as assistant. A survey of the water facilities of the Delhi mine is being made by Edward C. Uren, engineer, to determine the amount available for the operation of an electric-power plant. The Delhi was recently compelled to close because of lack of water for power. The property is controlled by the St. Gothard Gold Mining Co. Hamilton Eddie is superintendent.

Grass Valley, July 15.

The Alta drift mine, near Rough and Ready, has been bought by O. Scribner of San Francisco, who will open the old mine and work it systematically.

At the Pittsburg mine a 200-ft. winze is to be sunk to open the shoot of ore discovered on the south side of the shaft several weeks ago. The work of cutting the station for the engine on the 1300-ft. level is almost completed. When finished the engine will be installed and the other equipment will be put in place.

The Delhi Mining Co., owning the Delhi mine in the northern part of the county, near Columbia hill, is having surveys made to bring water into that camp. The company owns two valuable water rights, and these are to be repaired and improved, when there will be power for distribution in addition to that required by the Delhi mine.

Sierra County

J. M. O'Brien is operating the Tightner mine, at Alleghany, with the first long-distance hydro-electric power line, built by the Middle Yuba Electric Co. The plan is proving highly satisfactory, and is being watched by many mining men.

Reduction machinery has been ordered from Sacramento for installation at the Sovereign quartz mine, near Downieville. Two Beer's rollers, concentrators, and a complete cyanide plant are to be running by August 15 at the latest. F. O. Richardson is manager. The pay-shoot is at least 100 ft. long, it is reported, and a drift driven 50 ft. north shows good ore all the way. The Gibraltar's shaft is reported close to the gravel channel. It is down 303 feet.

Siskiyou County

The water-supply upon which placer mines depend in this region is already beginning to run short, and some of the mines are running on limited time and others are shut down until the fall rains come.

Trinity County

It is reported that the Bullychoop mine near Indian creek is to be reopened by a new company. The property is well equipped with machinery and is said to have a large amount of low-grade ore available.

Tuolumne County

(Special Correspondence.)—In the Black Oak mine, being operated by Charles E. Knox, S. A. Knapp, and John Bryant, the vein north of the big fault found on the fifteenth level (1500 ft. deep) has been followed by drifts to a point 210 ft. north of the fault. The vein shows an average width of 4½ ft. and averages $32 per ton. A cross-cut is being driven on the fourteenth level to cut this vein 120 ft. above the fifteenth level and to connect with a raise being made in the ore from the fifteenth to the fourteenth level.

Soulsbyville, July 15.

The Nautilus Gold Mining Co. has filed articles of incorporation. The company intends to operate the Haskins gravel mine, by driving under Table mountain. The operators of the Tappie mine near Tuttletown have found rich ore in that property. The quartz is said to be very rich in gold, but the extent of the discovery is as yet undetermined.

A company has been organized to bore for oil in the vicinity of Oakdale, between Warnerville and the Tuolumne river. The sinking of the first well will be commenced within a very short time. The company has secured a lease on 2000 acres of land for this purpose.

COLORADO

Clear Creek County

(Special Correspondence.)—Work is under way in the Oregon tunnel on Griffith mountain. Within 50 ft. it is expected a vein will be reached, supposed to be the extension of the Aetna. N. Williams is manager. The Kirtley mine on Leavenworth mountain will soon be among the shippers. Driving is in progress on an 8-in. streak of silver-lead ore, worth $78 per ton. E. S. Weaver is manager. The Black Prince mine on Pendleton mountain is the scene of an important discovery, a 4-ft. vein of ore having been uncovered that assays $40 per ton in gold and silver. Frank Winters is owner. Work was resumed this week upon the American Sisters mine, situated on Columbia mountain. The shaft is being unwatered and within a few days machine-drills will be used, as it is announced that sinking will be started. J. J. White is manager. Erickson & Co., leasing on the Smuggler mine, Brown mountain, are sending out heavy shipments of smelting ore, the average value being $40 per ton in silver and lead.

Georgetown, July 11.

(Special Correspondence.)—A streak of ore 7 in. wide has been cut in the shaft of the Neptune mine that assays $100 per ton in gold, silver, lead, and copper. J. M. Osborn is owner. The Dickson group of 13 lode claims has been taken over by the Cumberland G. M. & L. Co. The 100-ft. shaft has been unwatered and development started. J. I. Davis, of Pueblo, is manager. The shaft on the Powder House vein, near the portal of the Burns-Moore adit, is being unwatered, and driving is to be started east and west from the first level. J. M. Shaller is manager.

Idaho Springs, July 11.

Dolores County

The discovery of coarse gold on Dolores river 7 miles from Rico is reported, and numerous claims have been staked off. The field is said to be extensive and entirely unworked.

Gilpin County

(Special Correspondence.)—The shaft on the Santiago mine, in Russell district, has attained a depth of 250 ft. Sherman Harris is manager. A streak of talc 12 in. wide has been uncovered in the Elk Park adit that assays $79 per ton in gold. McCreer Bros. are owners. Wood Bros. have taken a bond and lease on the Lotus property and are cleaning out the adit preparatory to starting development. The property was at one time a producer. Development is in progress on the Central City mine and shipments will start soon. R. R. Demeter is manager. Heavy shipments are going out from the Anchor mine, being consigned to the Golden smelter.

Central City, July 15.

Lake County

THE TOMBOY MINE, NEAR TELLURIDE, COLORADO.

An important discovery of high-grade lead ore has recently been made in the Helena mine at Leadville, thus demonstrating that not all the ore has been found in this district of 34 years of continued success.

C. J. Moore has consolidated a large group of mines in the vicinity of the Clear Grit group and will begin the extensive development of the property. An adit 2500 ft. in length will be driven to develop the veins. In Leadville district many of the old mines are being reopened. The latest to be leased is the Rattling Jack on Breece hill east of the Ibex property and adjoining it. This fraction of ground has been leased at different times and generally some ore was found, but not in the large bodies which have been uncovered in the neighboring ground. A large amount of work has been done on the property on account of its close proximity to the Jonny. The new lease has been granted to W. E. Hollister and associates. An electric hoist has been placed and men are putting it in position. W. E. Hollister and associates are working a lease in the Ibex ground and probably have made as much money as any of the lessees during the past year and a half. They have been following the extension of the ore-shoot out of which Cortellini and Kyle made a large amount of money.

Ouray County

Negotiations are pending for the transfer of the famous Virginius mine and others of the Revenue group by the

Tomboy company at Telluride. The great veins of the Virginius group have been extensively operated through the Revenue tunnel, the portal of which is on the Ouray side of the lofty range. The evident intention is to work the Revenue group at first through the Ophir tunnel, which is near the Tomboy mill, and later to make deeper connections with the Revenue workings. The Revenue is credited with a production of over $15,000,000.

Al Conyers is developing a tungsten claim between Silverton and Gladstone, and reports that he has 4 to 8 ft. of ore that assays 61% tungstic acid.

TELLER COUNTY

The Cripple Creek Mohawk Mining Co. is preparing to build a mill of 75 tons daily capacity to be situated in the district. This company is operating a number of leases and ships the better grade of ore, but it has a large amount of ore which it is thought will yield a good profit if milled at the mines. The Rose Nicol Gold Mining Co. has shipped a car of milling ore to Colorado City from its mine on Battle mountain. The Saint Thomas mine on Beacon hill is to be operated by Charles Crowder, lessee. It joins the Gold Dollar mine. An ore-house is being built at the Jo Dandy on Raven hill. During June the Ajax Mining Co. shipped 1500 tons of $30 ore. A new mill for this company is about completed and will probably begin operations about August 1.

IDAHO

SHOSHONE COUNTY

(Special Correspondence.)—Two shifts at work on the 1000-ft. extension, which the Moonlight Mining Co. is driving on the Trade Dollar tunnel, to intersect its vein at a depth of 600 ft. below the old workings, are advancing 5 ft. per day. The Moonlight property adjoins the Hercules mine in the Coeur d'Alene. The company has a lease for 40 years on the Trade Dollar tunnel. The Gold Hunter mill near Mullan has resumed after a shut-down to increase its capacity from 150 to 300 tons per day. A sorting plant is being installed and will be ready in 30 days. The Hunter is in excellent condition.

Six acres of mineral land in the Yreka district in the Coeur d'Alene is the basis of an action filed at Wallace by the Caledonia Mining Co. against the Bunker Hill & Sullivan Mining & Concentrating Co. The Caledonia company claims the property under prior location and alleges that the disputed land was staked in 1887 as the O'Connor lode, to which it has acquired title. The Bunker Hill company applied last April for a patent to the United States Land Office for the Check and Wardner claims, which are surveyed to include the O'Conner claim.

It is reported that there are more men working in the mines in the Mullan district than in years. The Morning and Hunter mines are operating at a profit, and the Carbonate Hill, the Reindeer, and several others are in good condition.

Wardner, July 14.

MISSOURI

JASPER COUNTY

In extending a drift to the north of the Goodenough mine, on a sub-lease of the St. Louis-Joplin land, Wilcox and Rhodes have opened a rich run of blende and lead, that had been shown in the drill clippings which showed the ore to contain 7.8% blende and lead, the former predominating. The company is also drilling to the south of the shaft to determine the extent of the ore formation. The mine lies northwest of the Wilcox mines, and is in virgin territory. The nearest development is that of the Wilcox mines. The ore comes in at a depth of 174 ft. and continues to a depth of 200 ft., and a big pile of mill rock is accumulating.

Good ore has been found at a depth of 65 ft. in the Kramer mine at Cave Springs near Joplin. The ore has been penetrated to a depth of 10 ft. and carries 7 to 8% zinc. Southwest of Joplin a good run of ore has been found in the Grand Central at a depth of 160 ft. The ore is 20 ft. thick.

NEVADA

ESMERALDA COUNTY

Another effort is being made to find the downward continuation of the pay-shoot on the Blue Bull claim, if one exists. W. C. Cossar has re-commenced work on this ground after a long idleness. The workings are 400 ft. deep, but the new work is only 50 ft. below the surface, where an encouraging prospect has been found.

The shaft of the Florence American is to be sunk from 700 to 800 ft., when further search will be made for the ore-shoot that was worked several years ago in the upper levels of the adjoining Florence mine.

The development of mines, both old and new, in Tonopah continues without interruption, Montana Tonopah and Belmont being in the lead. A new company has been organized to develop ground presumed to contain the extension of the main vein of the Belmont mine. To prospect for this a deep shaft will be necessary, as the 'outcrop' of the vein is buried beneath about 1000 ft. of later volcanic rock. The property is known as the Halifax.

The work of building the new mill for the Belmont Mining Co. at Tonopah has commenced, the Young Construction Co. of Los Angeles having the contract. The mill will have a capacity of 450 tons daily. Water is to be pumped to the mill. The new plant is expected to be in operation next spring.

HUMBOLDT COUNTY

The Stall brothers are to extend their adit in their Canyon creek property near National an additional 200 ft., it now being in 300 ft. It is hoped this work will reach the vein, from the outcrop of which rich float silver ore was found some time since. An adit on the Neversweat mine on Buckskin mountain has run into rich silver ore. This ore was found 115 ft. below the surface. A discovery of good ore has been made in what is known as the Prout lease in the National Mining Co.'s property at some distance from any other known ore.

LINCOLN COUNTY

A recent deal has brought together at Pioche the Nevada-Utah, the Ohio-Kentucky, and the Consolidated Pioche companies. Negotiations regarding these properties have failed before, but it is reported that this time the papers have been signed. The Nevada-Utah, it is said, now holds about 1000 acres of the heart of the Pioche camp.

NYE COUNTY

The official report of the Round Mountain Mining Co. shows that during the quarter ended May 31 the company mined and milled 8559 tons of ore at a total cost of $54,715.27, a cost per ton of $6.39. From the ore milled was recovered gold to the value of $85,196.24, or $9.95 per ton, from which was netted a profit of $3.56 per ton, or a total profit of $30,480.97. On May 31 the company had cash on hand and bullion in transit of $89,154.85. The installation of the milling machinery is completed. The new mill has been in operation since July 5, and has increased the tonnage from 100 to approximately 150 tons per day, which will reduce the cost per ton. Mine conditions generally are much the same as reported on March 1. The development of one of the veins mentioned in the last report as having been opened in the 700-ft. crosscut has commenced. Sufficient work has not yet been done to determine its worth, but it is now producing 10 tons per day of a little higher value per ton than the average mine-run of ore.

STOREY COUNTY

During the second week in July the Union and Mexican mines produced ore having an assay value of $28,958.57, of which the Mexican produced $17,093.67 in 4 days. The Ophir in the same period produced 295 tons of ore of an average assay value of $40.22 per ton.

The most important recent development in the Mexican mine was the extension of an east cross-cut through a dike into ore on the hanging-wall side. This demonstrates that the ore-bearing formation is even wider than had been anticipated. This is on the 2500-ft. level, and preparations are being made to sink a winze below that level where a small electric hoist will be used. Stoping continues on the 2400-ft. level, and a stope is being opened on the 2500-ft. level. The joint cross-cut on the Mexican-Union line is going ahead in low-grade ore. The outlook is described as most promising. Construction on the New Mexican mill is about to be commenced. The sump of the C. & C. shaft, below the 2650-ft. station, is being cleaned out and an east cross-cut will be driven from the level. These workings are far to the west of the contact along which the Mexican-Union orebody is being developed. On the Gould & Curry arrangements are being made to ventilate the upper workings in the Geyer lease where there is a large amount of low-grade ore. Lessees on the Monte Cristo are shipping ore to the Fischer mill in Six-Mile canyon. At the Ward shaft the usual operations are under way, to control the water and permit further prospecting.

NEW MEXICO

Socorro County

During the latter half of June the bullion product of the Socorro mines amounted to about 34,000 oz. Ore treated for the month was about 4100 tons, the decrease being caused by breakdowns at the power-plant. The mill continues its better than 92% recovery. Drifts on both the 600-ft. and 700-ft. levels are being pushed. The Ernestine Mining Co.'s bullion clean-up for the last ten days of June was 9522 oz., with 5 tons of high-grade concentrate. Last week's tonnage was 564, with 38 sacks of concentrate. The mill was closed down for the celebration on the 4th and 5th, causing the lessened ore treatment. The plant now has an abundance of water. At the Deadwood mines the greater part of the ore treated comes from the third level, which doubles the value of the mill-feed. A representative of the De La Vergne Engine Co. is on the ground, adding a new attachment to the engine, which is said to be a very material improvement. Preparations are being made to do considerable development on the Trilby group of claims, with a view to treating the ore in one of the local mills. Good progress is being made in driving the lower adit of the Gold Dust mines, which will intersect the vein at a depth of some 800 ft. from its outcrop. Drifts along the vein of the Maud Mining Co. have been started from the new two-compartment working shaft.

PENNSYLVANIA

Allegheny County

(Special Correspondence.)—The School of Mines of the University of Pittsburg was reorganized in 1908. Since then the results have been such that within three years a new mining building, costing $175,000, has been erected, equipped, and occupied. The attendance has been raised from 8 to 72, the faculty increased from 2 to 18, and the graduating class from 1 to 18. Its graduates now number 32, against 7 during the 13 preceding years. The Governor of the State has recently approved a bill giving a $400,000 appropriation to the Schools of Mines and Engineering.

Pittsburg, July 15.

UTAH

Salt Lake County

(Special Correspondence.)—Plans are being considered for the reopening of the once noted Emma mine near Alta. The property, sold to an English company for several millions of dollars in the early 70s, is now owned by Jesse Knight, of Provo, and his associates. What is known as the Snake Creek tunnel is being driven steadily forward, its object being to furnish a drainage and haulage outlet for the western portion of the Park City district. On July 2 the adit was in 3423 ft., an advance of 251 ft. having been made during June. The Daly-Judge mine will be greatly benefited by this drainage adit, as it will make more cheaply available much ore which is below the drainage level. The Ontario company is increasing its working force. The Daly West has paid its second quarterly dividend of $54,000 for this year, making a total of $6,201,000 to date. The Silver King is developing a fine body of ore that was recently discovered. The Thompson and West Quincy companies have been merged under the title of the Thompson-Quincy company. Development is progressing. This property will be benefited by the extension of the Ontario drainage tunnel. It is reported that 2000 men are at work in the Park City district. The Scott Hill group of mines, that for 27 years has been idle, has been bonded to the Barry Coxe Mining Co., and development has been commenced.

Alta, July 15.

WASHINGTON

Ferry County

(Special Correspondence.)—Large reserves of ore are being opened in the Surprise and Lone Pine mines by the Republic Mines Corporation. In driving the Jim Clark adit on the Surprise 42 ft. of ore was intersected which assays $8 per ton. Shipments were made to the Tacoma smelter that must have assayed over $12 per ton to cover the expenses of mining, transportation, and treatment. A drift has been driven on it about 50 ft. The vein on this level has been explored 300 ft. northerly and about 200 ft. southerly. The samples assayed June 6 are reported as follows: $12, $51, $37, $42, $1, $2, $39, and $93. The last mentioned came from 35 ft. across the foot-wall side of the Bonanza shoot, below the intermediate level, which is between the 120 and 200-ft. levels. The shoot has been stoped about 12 ft. in width, and from 5 to 8 ft. of ore still remains on the foot-wall side of the shoot, in place. It is believed that this unbroken ore will average in value about $35 per ton. Some of the rock shows gold. The winze below this level is being sunk at the rate of 5 ft. daily with two machines. On the intermediate level a drift runs 100 ft. northerly and 400 ft. southerly from the winze, and three drills are used for stoping ore. On the 200-ft. level the vein has been developed about 300 ft. in length, and the samples are reported to assay from $14 to $40 per ton. The main incline shaft is down 215 ft. where ground is being broken for a station. A raise is being made from the 600-ft. level, which connects with the 500-ft. level of the Quilp mine, following up on the rake of the pay-shoot.

CANADA

British Columbia

It is announced that T. W. Beam has an option on the Nugget mine on Sheep creek near Nelson. The property is being thoroughly investigated by engineers. It is equipped with a small mill.

MEXICO

Sonora

The Cananea Con. Copper Co. has resumed the development of the Puertocitos mine in the west end of the camp. Some recent prospecting has met with very satisfactory results, and extensive operations there are now expected. The mineral zone is 800 ft. wide with a band 200 ft. wide in the centre, which is thought to run through the mountain, and is probably the same as the mass of ore found on the farther side of the hill. The ore deposit is nearly flat and is mined in a series of benches. This property is seven miles by rail from the smelters. Official reports show that a great many denouncements have been made in Sonora this season, which is an unmistakable indication of an increasing interest in mining in this State. The El Triunfo company has shipped a carload of high-grade matte to the El Paso smelter which is the product of the wood-burning reverberatory-furnace at Arizpe.

The Aguascalientes smelter, one of the largest in the world, of the American Smelting & Refining Co. has been shut down indefinitely. There were eight copper and two lead furnaces and four copper converters, with a capacity of 1500 tons daily. The smelter at Chihuahua has been ordered closed down indefinitely. Large mines, of the same company, at Santa Eulalia, producing silver-lead carbonates, silicates, and calcareous ores, also have been ordered closed. There are seven shafts there.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

G. H. Garrey is in San Francisco.

J. H. Curle was in San Francisco.

F. H. [illegible] has returned to San Francisco.

F. F. [illegible] was in San Francisco early this week.

J. B. Farish was at the St. Francis, in San Francisco.

Frank B. [illegible], Jr., is making a brief visit to the Comstock.

E. B. Gage of Phoenix, Arizona, is at the St. Francis, San Francisco.

Scott Turner is traveling through Norway. He will also visit Spitzbergen.

C. S. Herzig was at Manaos, Brazil, during June, and has gone to Iquitos.

Robert H. Richards has gone to Houghton, Michigan, on a month's professional work.

T. H. Minor, who is interested in oil properties at Bakersfield, is in San Francisco.

Sidney L. Galpin, of Cornell University, is doing summer work in geology in western Virginia.

L. A. McIntosh, superintendent of the Midas mine, Shasta county, is stopping at the Stewart hotel, San Francisco.

Francis A. Crampton has resigned from the position of chief engineer for the Arizona Copper Belt Mining Company.

W. R. Feldtmann has taken into partnership James A. Macteak and H. L. Sargent. The name of the new firm is W. R. Feldtmann & Co.

J. W. Finch has returned to Denver from Telluride, where he has been carrying on extensive investigations for the Liberty Bell and Smuggler Union mines.

Fred V. Burns has resigned as mine superintendent for the Veta Colorada M. & S. Co., to accept the position as manager for the Bueno Fé Mining Co. at Ojuelos, Jalisco.

George D. Hubbard, head of the department of geology at Oberlin College, has charge of the work in geology and geography at Ohio State University during the summer session.

F. Rutherford, assistant superintendent at the Copper Queen smelter at Douglas, has resigned to take the position of superintendent of the smelter at the Detroit Copper Mining Company.

Frank L. Sizer, superintendent for the Balaklala Con. Copper Co., will resume consulting work, now that the Balaklala smelter is closed, but for the present he is at Coram, Shasta county, California.

Obituary

Among those whose lives were lost in the forest fire at Porcupine were Robert Alvin Weiss, engineer in charge of the West Dome for F. A. Heinze, and his wife and little daughter. Mr. Weiss was an engineer of considerable experience.

Nicholas Densmore, a prominent contractor and mining man, died, June 10, of smallpox in the little village of Umala, near the Chacarilla copper mines of Bolivia, where he had gone on business relating to some important mining claims in which he was interested. Mr. Densmore was a native of Minnesota, but spent the greater part of his life in railroad construction, and for the past fifteen years had been in South America. For the past three years he had devoted his time entirely to his mining interests in the Quimza Cruz mountains and the Chacarilla copper region. So far his associate, Joseph Bolan, has been unable to get into communication with any relatives of the deceased.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

Life Insurance—Visiting Mine Not a Forfeiture

A condition in a benefit insurance certificate containing a prohibition against the insured engaging in prospecting or mining, is not violated and the insurance is not forfeited by merely visiting a mine.

Butler *v.* Supreme Court, etc., Independent Order of Foresters, (Washington), 110 Pacific, 1007.

Recovery for Willful Violation of the Mining Statute

In an action for the death of a coal miner under the Illinois statute, an instruction to the effect that a recovery could be had for any injury or death of which the willful violation of the mining statute by the mine-owner was the proximate cause, was not misleading as authorizing a recovery for any violation of such mining statute, regardless whether such violation was alleged in the complaint, where other instructions stated fully that there could be a recovery only for violations of a statute as charged in the complaint.

Belskis *v.* Dering Coal Co., (Illinois) 92 Southeastern, 575.

Taxation of Minerals

The statute of Kansas providing for the taxation of strata of minerals in land the title to which has been vested in persons other than the owner of the surface, applies to oil and gas as well as to solid minerals; and under this statute where the different strata are severed by a conveyance or otherwise, each stratum is subject to be taxed separately as real property, and it is the duty of the owner not only to record the instrument which conveys the property to him within the time specified, but also to see that it is duly listed for taxation at the proper time. On this principle, an instrument called a lease, by which the owner of the land grants, conveys, and warrants to another all the coal, oil, and gas under a certain tract of land, operates to sever the coal, oil, and gas from the remainder of the land and the interest segregated and conveyed is subject to be separately taxed, and it was the duty of the owner of such interest to list it for taxation.

Mound City Brick & Gas Co. *v.* Goodspeed Gas & Oil Co., (Kan.) 109 Pacific, 1002.

Purchase of Mining Claim by Mortgagee as a Trustee

A mortgagee of an unpatented mining claim agreed with the judgment creditor of the mortgagor to foreclose his mortgage and purchase the claim, and to hold the title in trust to protect the parties under their liens, and to do at his own expense the necessary assessment work to maintain his title. Pursuant to such agreement he foreclosed his mortgage and purchased the claim at a foreclosure sale and executed an instrument reciting that as trustee for himself and the judgment creditors he had so purchased the claim. Under this agreement the mortgagee was vested with the legal title in trust and could not abandon the performance of his duty as trustee without rendering himself liable to the judgment creditors, though he could convey his interest which he had individually in the subject matter of the trust. Neither could he substitute another in his place as trustee without the consent of the beneficiary, but must proceed in the execution of the trust, and he is not permitted to terminate it by his own act or default. And where he failed to do the assessment work according to the agreement, the judgment creditor, the beneficiary, could himself do the assessment work and tack the expense on to his lien. But where such mortgagee as such trustee employed one of the judgment creditors to supervise the assessment work at a monthly salary, the claim of such creditor for salary and for any damages while in the performance of such duty was personal against the mortgagee alone, and recoverable only in an action at law.

Anderson *v.* Phegley, (Oregon) 110 Pacific, 975.

GEOLOGY OF THE NEW YORK CITY (CATSKILL) AQUEDUCT. By Charles P. Berkey. Bull. 146, New York State Museum, 1911. 283 pp.; maps, ill. In the construction of the Catskill aqueduct the board of engineers used commendable foresight in engaging the services of a board of consulting geologists, J. F. Kemp, W. O. Crosby, and C. P. Berkey. With their aid the difficult problem of crossing the Hudson river canyon is being successfully solved, as well as many other geologic engineering problems. Mr. Berkey, by arrangement between the Board of Water Supply and the State Geologist, has been enabled to present in this volume the results of the notable geologic work of the board, which will be of equal interest to geologists and civil engineers.

The following publications of the United States Geological Survey have recently been received: 'Some Stream Waters of the Western United States,' by Herman Stabler; Water-Supply Paper 274, pp. 188, index, 1911. EDITORIAL

AFTER August 1 the home of the *Mining and Scientific Press* will be at 420 Market street, San Francisco, but a short half block from the sites where for twenty five years it was domiciled. Driven from Market street in 1906 by the fire which swept away our offices, we took refuge in Berkeley for a year, returning to San Francisco as soon as circumstances would permit. Our growing needs now demand more commodious and suitable quarters than were available during the period of reconstruction, and we return to a neighborhood full of associations. Perhaps the best feature of the change is that it makes us more accessible to our friends, our most valued possession. At 420 Market street the latch string will always be out.

CONDITIONS in Haiti are much disturbed. President Simon is likely to be deposed, and it is not impossible that foreign intervention may be necessary.

INTERNATIONAL LOANS seem a popular method of securing international amity. A $2,000,000 international loan is now to be made to the Republic of Liberia, in which Germany will participate.

FURTHER evidence of the useful service being rendered the mining industry by the Bureau of Mines is afforded by the appointment of Mr. F. G. Cottrell to take charge of a special investigation of the smelter fume problem. Mr. Cottrell is well known from the notable work he has already done upon this problem in private research, and the Bureau of Mines is to be complimented upon its choice.

DISCREDIT is cast upon European journalism by an article which recently appeared over the signature of A. Polli, editor of the *St. Petersburger Politische Korrespondenz*. One quotation will suffice: "Americans have captured the sympathy of the Chinese by the return of the Boxer indemnity, *in which their demands were much larger than those of other nations*, and were, to their surprise, at once paid in full." The italics are ours; comment is superfluous. The term 'yellow journalism' is of American origin, but the deep saffron variety of the article is produced abroad, apparently.

DECISIONS by the courts of New South Wales sustaining the patents of the Minerals Separation, Ltd., in the suit brought by the owners of the Elmore process, are of interest to many mine owners in America, the more so since the former company has recently opened an office in the United States under the management of Mr. E. H. Nutter. Flotation processes are of much interest, but the legal entanglements involved in the basic patents have been so protracted that outside of Australia the most notable results so far have been the separation of friends. In Australia much good work has been done, and there is every reason to believe that in many districts in America, especially in Colorado, ores exist to which flotation processes can be applied with advantage. Further developments will be awaited with interest.

A NEW FIELD for the 'Get-Rich-Quick Wallingfords' has been opened up by the discovery of a commercially practicable method for manufacturing paper from bamboo pulp. Heretofore the bleaching process, by means of caustic soda, has been very expensive, but this method has been obviated. A bamboo field can be cut-over annually for an indefinite period and yields a cheap, strong fibre easily collected for transportation. The Panama zone and Porto Rico offer great possibilities in bamboo culture. Aside from the probable organization of innumerable 'bamboo paper companies', the increasing demand for paper-pulp and the diminution of the forests lend great interest to this new source of paper production.

ANOTHER instance of German progressivism is seen in the proposal to appoint technical ambassadors to foreign capitals, with the rank of councillors of legation, whose duty will be to watch technical progress in the country to which they are accredited. It is to be hoped that the United States may follow, even though far behind. The present American consular reports are, to quote Leclere's phrase, used in another connection, "*remplis d'inutilites et d'inexactitudes.*" Until recently the United States had no commercial attachés to her Oriental legations, though no petty European country was too poor to afford such an official. The recent appointment of a well known commercial journalist as commercial attaché to the legation at Peking is a notable step in advance. Further progress is desirable.

THE SITUATION in the financial centres of the East becomes, if possible, more complex. The present month shows a tremendous disbursement of dividends, and the latter part of last month saw a revival of stock market activity, which in some quarters was said to be 'window dressing.' That this analysis was correct is shown by the fact that on one day of the past week the trading on the New York Stock Exchange fell away to smaller volume than on any full day in the past eight years. The larger pools and the heavier operators, alarmed at this exposure of utter lack of public interest, rallied to the support of the market, not as to prices, but as to the total of trading, and complete stagnation has been so averted. The mining situation in New York is equally complex. The open market for mining shares on the New York Curb promised at one time to grow into an institution of great importance. Now this market is dying, losing prestige, and the traders are forced upon a ruinous basis; living or trying to live by trading upon each other, as distinguished from trading for the account of legitimate customers. This market place is now shunned by those who have stocks to distribute, and in a way the mining interest in New York suffers on account of this state of affairs. The Porcupine issues launched in New York have nearly all stuck on the ways, and the trading, so far as any distribution is concerned, is wholly negligible.

DIFFERENT views of the same subject are of much interest. Mr. W. S. Kenyon, senator from Iowa, in a speech in the Senate, made the following observations on American living conditions: "We are living in an extravagant age. We are money mad and racing through life at a neck-breaking pace, piling up fortune on fortune, men worth millions striving for more, never stopping to think there is no pocket in the shroud. The rich are flaunting their riches in the faces of the poor. We see a $120,000 organ at the opening of a millionaire's home in New York and a long line of hungry men at midnight in the same city, constituting the bread line. Girls working in stores for $5 a week, and the proprietor of such stores dying and leaving millions to museums. It it any wonder that the people of the country are restless? The problem of the control of great wealth is the most important problem of the hour and the one that should receive our attention." An English writer in *Tit-bits* sees them in this light: "In America the builder, the engineer, the house-painter, the printer and compositor earn double the wages paid to such trades in this country. Also they work shorter hours and have better homes. No artizan walks the streets of an American city in his workman's clothes. He changes them for decent attire as soon as his job is finished. The American workman is both self-respecting and independent. His British brother is given to 'shirking' and beer-drinking."

Truth is Good Enough for Honest Folk

Boomers of Porcupine shares are resorting to full-page newspaper advertisements to galvanize into life a dead speculative market. Such methods are not warranted and are likely to prove futile. We have a high opinion of Porcupine and have no doubt whatever that much money will be made there, both in mining and in shares. But we must protest against such drivel as the following, printed in display type by the Chicago *Inter Ocean:*

"I have stood on the brink of the great Treadwell mine of Alaska and saw hundreds of men quarrying out the low-grade ore which keeps a thousand stamps in the never ending task of reduction. I have gone through the Homestake properties in Lead City and saw where millions were gained by quantity and scientific application for value recovery; I have held my candle to the face of quartz veins in California, Mexico, British Columbia, and Alaska which seemed 'splattered' with gold; I have peered into drifts which gave the appearance of treasure vaults; I have seen boxes cleaned in a placer camp and watched the men lug away the yellow dust; I have permitted my ecstasy to have full sway as I looked upon the gold beribboned face of the Truett-Mohawk lease in Goldfield; I have seen Cripple Creek rise from a desolated wilderness to a great active camp; I have peered in the face of every mining claim of renown and trod upon the surface of every camp of fame, and with the experience gained by years of travel, investigation, and investment feel that I am qualified to express an opinion. Let me set it forth here, for the benefit of friends and for those who do not know me, and all I will do is to repeat what has been said by every mining man whom I have met in this camp: 'The Porcupine is the greatest gold camp on earth'."

This is published as an introduction to a description of the district by Mr. N. H. Truett, whose competence to judge is sufficiently indicated by the extract. To those not familiar with Chicago newspapers it is worth noting that the *Inter Ocean*, once a great paper, is now the personal organ of Mr. William Lorimer. Having served in turn Mr. Yerkes while wrecking street railroads, and Mr. Walsh while wrecking banks, it is appropriately engaged in a search for widows' nickels on behalf of 'sure-thing' promoters.

Canadian Reciprocity

The bill providing for reciprocal exchange of goods between Canada and the United States has passed Congress, and, when signed by the President and sanctioned by the Dominion Parliament, will become the law. Journals which are in favor of free trade, the country over, will now proceed to demonstrate with learned arguments that trade between the adjoining countries will be enormously benefited, while those of the opposing faction will, with equal logic, point out that the commerce of the United States will be greatly injured by the new arrangement. To one who looks upon the political game with a mild interest, tinged with cynicism, the new law appears rather as a mighty effort of the administration to create a political issue for the approaching presidential campaign. The present administration went into office attended by a general public belief that a conservative and forward policy would be followed. It will retire attended by a sense of disappointment. In many respects the Taft administration has been unfortunate; its actions have been misunderstood and even misrepresented, but the general public belief that certain corporations have had too much influence in its acts and policies can neither be refuted nor denied. The tariff revision of 1909 was a breach of faith with the American people; it remains to be seen whether the attempt to divert their thoughts by the securing of free trade with Canada—in other words, giving the people complete reduction of duties where it can have little or no effect—will be successful. Public interest and attention in the United States belongs to the genus *Ephemeridae*, and it is not impossible that the attempt may succeed. On the other hand, the growth of ideas of social democracy and the strong public sense of the need for fundamental legislation to check the growth of monopoly, may easily combine to cause a Democratic victory at the next presidential election. Changes of political administration have usually coincided with periods where important issues were at stake, and have almost invariably been either preceded or followed by grave industrial disturbances. The industrial system is interconnected like a mighty power system. Mechanics may argue at length as to the relative merits of Corliss and other types of valve gearing, but while one type is being taken out and another substituted the machinery must stand idle and will not run smoothly until some time after it is restarted. At a political gathering it is customary to extol the great wisdom of the founders of the Republic. Adherence to sober fact recognizes in them men chiefly distinguished by patriotic zeal, who achieved astonishingly good results, when it is considered how little in consonance with their preconceived ideas our country has developed. It might have been expected that a method of government devised for the civilization of 1789 would be absolutely unfitted for the civilization of 1911, but it is only inadequate and unsatisfactory. From the editors' window there is visible a building that in 1906 was ruined by the earthquake and fire, though it remained standing. Workmen have since been busy, and girder by girder, brick by brick, one piece at a time, the building has been reconstructed until now it is a fair habitation. The government of the people, by the people, and for the people, which has proved in practice to be of the people, by the covert representatives of private interests, in the interest of corporations, needs similar treatment.

Fuel

The growing use of fuel oil in industrial work prompts us to make some observations upon fuel and its uses. Fuel is defined by the Standard Dictionary as "combustible matter used to kindle or sustain fire, or produce heat"; thus placing the cart before the horse, as the only rational purpose of kindling a fire is the production of heat. The idea of fire, or combustion, is essential, however, for heat may be obtained commercially without the use of fuel, as by exposure to the sun's rays, or by the use of the electric current. Since the idea of combustion is fundamental, and since we live in an atmosphere of dilute oxygen, it follows that fuels may be defined as substances capable of undergoing oxidation, with the concomitant production of heat. There are numerous substances possessing this qualification, but their characteristics, in many cases, unfit them for practical use. Pyrite, for example, can be readily oxidized, with the production of heat, but the products of combustion are an objectionable gas and a bulky residue of iron oxide. Carbonaceous substances, on the other hand, yield CO_2 and water vapor, the only residue consisting either of the impurities originally present or a small amount of unburned fuel. As a matter of practical convenience, based on this and other factors, fuels are carbonaceous substances either solid, liquid, or gaseous.

The commonest fuel is wood, which has been used for that purpose since primitive man first contrived to light a fire. Since this is bulky and contains much water, which puts a limit upon the intensity of the heat attainable, charcoal came to be used, giving a more intense heat and being more easily transported. Following up this advantage, coal and coke came into use. The use of the solid fuels is conditioned by six principal factors: the character of the gaseous products of combustion, the character of the solid residue, ease of transport, the amount of heat available per pound of fuel, the degree to which this heat can be utilized, and the ratio between the total heat per pound of fuel and that which can be utilized. To mention only a few examples, the pungent reek of peat and the heavy smoke of bituminous coal are disadvantageous, as are the large amounts of ash produced by the combustion of many anthracites. The greater number of heat units present in coal give it a great advantage over peat, while the friability of the latter, a character which it shares with many lignites, renders its transportation a difficult matter. The heat which can be utilized depends so largely upon the methods adopted, more particularly the type of boiler employed, that generalization is difficult. Anthracite has a higher fuel ratio than lignite, yet a boiler under which lignite can be satisfactorily burned would give unsatisfactory service with anthracite.

Liquid fuel, which for practical purposes, means the heavy petroleums which occur naturally in some districts, notably in southern California, meets admirably the factors given for solid fuel. It has a high fuel value, little residue, and the products of combustion are unobjectionable. The factors which militate against its use are commercial. Until recently no sufficient supply was available, so that it was not worth while to install types of boilers and burners adapted to its use. Even yet a supply is not universally obtainable, and as it can neither be so easily nor so cheaply transported as coal, its use is likely to remain localized. But where a cheap and abundant supply is available, liquid fuel is remarkably satisfactory in practice. Before a solid fuel can burn it must be converted into gas; strictly speaking, combustion is the burning of the gaseous products given off by a highly heated fuel. Since a liquid fuel is more easily converted into a gas, it is more easily burned. The burning of a gaseous fuel may be regarded, then, as merely the isolated second stage of ordinary combustion. This is well shown in the manufacture of producer gas in one apparatus, and its combustion in another. The burning of natural gas may be looked upon as a similar process, in which the time interval between production and combustion is very great. Natural gas unfortunately occurs in but few localities, and the means necessary for its transport closely circumscribe its use. A further disadvantage is the fact that it has been found that the duration of the flow of a gas well is so brief that industries founded upon the use of this cheap and satisfactory fuel have in some cases come to an untimely end. With the advance in mechanical methods, however, it has been found that the most economical method of utilizing solid fuel, in all cases where the size of the plant justifies the necessary expenditure of capital, is to generate gas from solid fuel; burning the gas, or using it in gas engines. German engineers have led in the experimental development of the latter, but the development of the gas-engine industry bids fair to repeat that of the automobile, where European manufacturers led in experimental development, only to be eclipsed by the standardized development in the United States.

Graphic Solution of Fault Problems

By C. F. Tolman, Jr.

(Continued from page 810, Vol. 102.)

Elementary problems in line and plane intersections to show the application of the two-level method of projection. (Fig. 1 to 4.)

Problem 1. Fig. 1.—**Given two parallel planes cut by a third plane. To find the shortest distance (both magnitude and bearing) between the two planes measured on the third plane.**

Analysis.—Revolve the traces of the intersections of the parallel planes with the third plane into the horizontal position. Draw a perpendicular between these traces and revolve back into the original position.

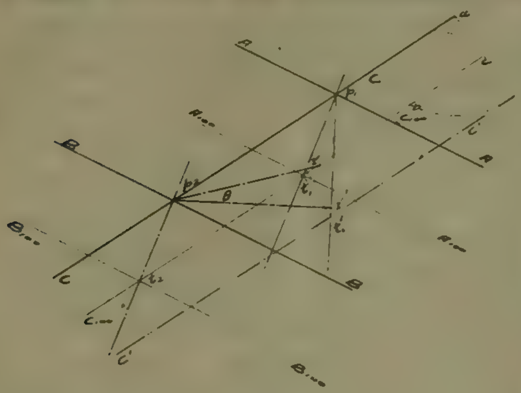

FIG. 1.

Construction.—AA and BB are the strike lines of the two parallel planes whose dips (45° in this case) are shown by the contours $A_{100}A_{100}$ and $B_{100}B_{100}$. CC and $C_{100}C_{100}$ represent the strike and dip of the third plane.

The strike lines AA and CC intersect at p_1 and the contours at t_1. p_1t_1 is the projection of the intersection of these planes, and p_2t_2 that of the second plane with plane CC. Construct the dip triangle *abc*. *ab* measures the distance $C_{100}C_{100}$ from CC when the plane is revolved about its trace into the surface. Such a revolution will cause p_1t_1 to take the position p_1t_1'. Draw p_2r' perpendicular to p_1t_1', and then revolve CC back into its original position, when r' falls on r.

p_2r' gives the length of the desired measurement.

p_2r is its projection and gives its bearing.

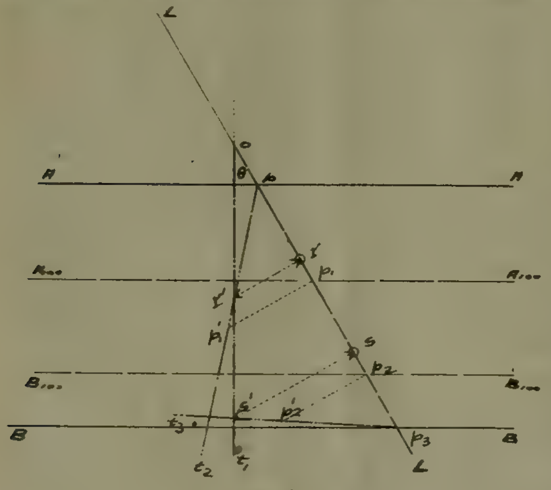

FIG. 2.

Problem 2. Fig. 2.—**Given two planes and an intersecting line. To find the points where the line pierces the planes.**

Analysis.—Take an auxiliary vertical plane containing the given line and revolve it into the horizontal position. The intersections of the traces of the given planes on the auxiliary plane, with the line, locate the desired points.

Construction.—*LoL* is the given line piercing the surface at *o* with a dip of Θ. AA and BB are the strike lines of the given planes with their dips shown by the contour lines. **Pass the auxiliary perpendicular plane through *LoL*** and revolve it into the horizontal position about *LL*. ot_1 is the revolved position of the line *LoL*. The traces of the given planes on this plane are found by dropping perpendiculars (scaling 100 ft. in length) from p_1 and p_2 (points situated at the intersection of the contours with the auxiliary plane). Therefore pt_2 and p_3t_2 are the desired traces, and r and s are the projected positions of the points where *LoL* pierces planes *AA* and *BB* at depths respectively of *rr' and ss'*.

Problem 3. Fig. 3.—**Given three points. To find the plane containing them.**

Analysis.—**Draw two perpendicular construction planes,** each containing a different pair of points, and rotate the planes to the surface. Draw a line passing through the pair of points in each construction plane. The points where these lines pierce the surface determine the strike-line of the plane, and its dip is shown by passing the contour parallel to the strike through the projection of a point 100 ft. below the surface on either one of the lines.

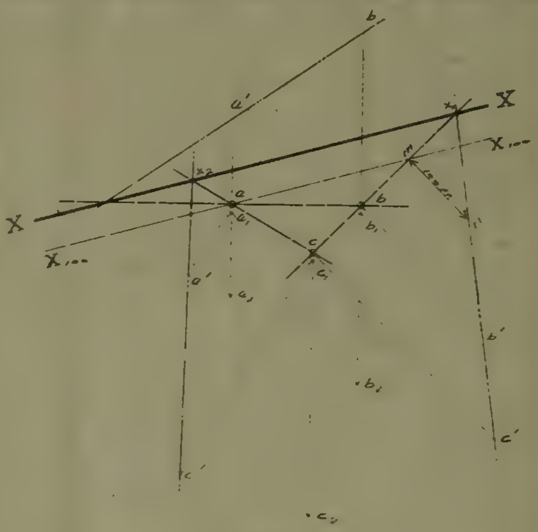

FIG. 3.

Construction.—a, b, and c are the given points whose distance below the surface are, respectively, a_1a_2, b_1b_2, and c_1c_2. Pass perpendicular planes through *ac* and *bc* and revolve them into the horizontal position. x_2c' and x_1c' are the revolved positions of the lines in each plane containing the respective pair of points ($aa' = a_1a_2$, $cc' = c_1c_2$, etc.). The surface trace of the desired plane passes through x_1 and x_2, and its contour is located by point m, which is the projection of a point on the line passing through b and c, 100 ft. below the surface.

Problem 4. Fig. 4.—**Given a line and a point. To find the plane containing them.**

Analysis.—The strike-line of the desired plane must pass through the point where the given line pierces the surface, and be parallel to a line drawn through the projection of the given point, and through the projection of a point of equal depth situated on the given line. The plane contour passes through the projection of a point on the line 100 ft. below the surface.

Construction.—*LoL* is the given line with a dip of Θ, and a the given point at a depth a_1a_2 below the surface. p is the projection of the point p' on the line *LoL* and taken at a depth of [illegible] as this happens to be just 100 ft., the contour of the desired plane passes through these two points and the strike-line is XX parallel to the contour and passing through [illegible]

FAULT PROBLEMS

Fault movement that of pure translation; fault plane vertical. (Problems 5, 6, and 7.)

Problem 5. Given a vertical fault plane and the strike, dip, and total heave of two faulted strata. To find amount and direction of total displacement.

Analysis. The fault movement separates the traces, on the fault plane, of the two strata on one side of the fault, from the traces of those on the other side; therefore a line connecting the intersections of the traces determines the amount and direction of the total displacement.

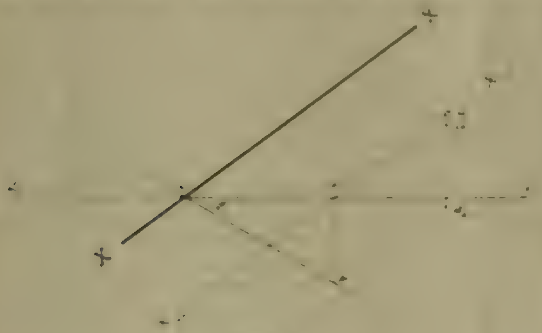

FIG. 4.

Construction.—The fault plane *FF* is vertical and *AA* and *A′A′* are the two portions of the faulted stratum whose total heave = *O*, and *BB* and *B′B′* of the second stratum whose total heave = *BB′*. Revolve the fault plane *FF* about its strike-line into the horizontal position. *ab* is drawn at a distance of 100 ft. from *FF*, and therefore is the revolved position of the 100-ft. contour of the vertical fault plane. *a*, *b′*, and *b* are at the intersections of *ab* with the contours of the faulted strata. *AA* and *BB* are the revolved positions of the traces of *AA* and *BB* on the fault plane and intersect at *C*. Likewise the revolved traces of *A′A′* and *B′B′* intersect at *C′*. Before faulting, *C* adjoined *C′*. Therefore the total displacement = *CC′* in amount and [illegible] = the angle it makes with the horizontal.

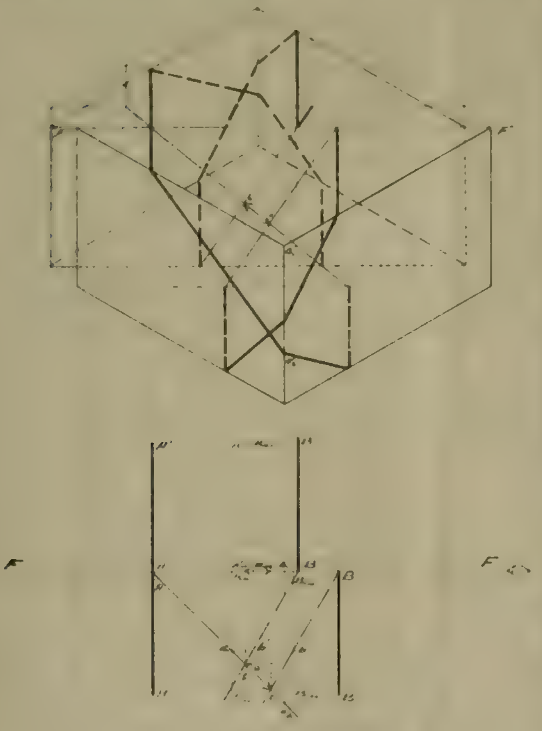

FIG. 5.

Stereogrammatic representation of this problem is shown above in Fig. 5. The graphic solution, beneath can be projected on the isometric block in the following simple manner. Make the 'long diameter' of the block *F′F′* parallel to *FF*. Then all points on *FF* (Fig. 5) can be projected directly on *F′F′*, for the long diameter is projected full length. To find, for instance, point *a′* on the stereogram in order to draw in the front trace of *AA*, measure its true distance a_1a_2 in the lower figure and diminish it according to the isometric ratio, giving the distance $a_1'a'$. In the upper figure the elevated block is supposed to be cut down to a level with the other block by erosion, but the removed upper portion with traces is shown in light lines.

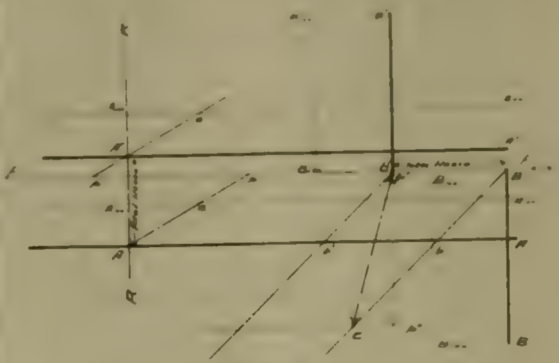

FIG. 6.

Problem 6. Fig. 6. Given a perpendicular fault plane, and the dip, strike, and total heave of two faulted strata, one whose strike is parallel and the other perpendicular to the fault. To find the total displacement.

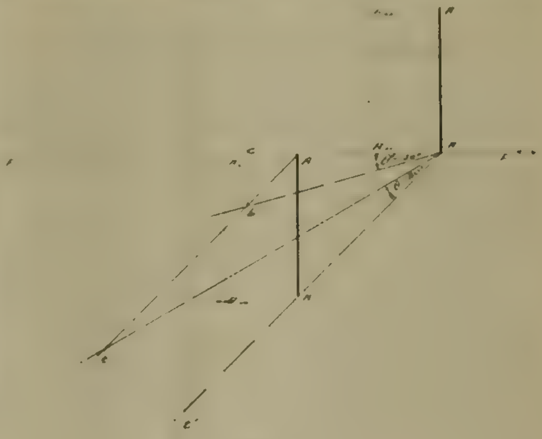

FIG. 7.

Analysis.—Fault *FF* is a strike fault when considered in reference to the parallel stratum, and a dip fault in reference to the stratum with perpendicular strike to the fault.

By passing a vertical plane normal to the fault plane, the vertical displacement of the fault is found, and from this, the total displacement which separated the traces of the second stratum on the fault plane, is found.

Construction. Pass a construction plane *RR* perpendicular to the fault strike *FF*. *Aa* and *A′a′* are the revolved traces of *AA* and *A′A′* on *RR*. Continue the traces until they intersect the fault trace on *RR* and at *p* and *p′*.

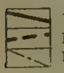
Then pp' is the vertical displacement. Revolve the fault plane on its strike-line FF into the horizontal position. The revolved traces of BB and $B'B'$ on the fault plane are Bb and $B'b'$. Lay off $p'' p'' = p'$ (vertical displacement). The total displacement is $p''c$.

Problem 7. Fig. 7.—Given a perpendicular fault plane, the dip and strike of both portions of a faulted stratum, the total heave, and the direction of fault movement *(a)* Θ is measured downward from the parallel displacement, *(b)* Θ is measured upward from the horizontal displacement. To find the total displacement.

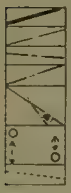
Analysis.—The distance between the traces of the two portions of the faulted stratum on the fault plane in the known direction (often told by fault striæ) of fault movement, is wanted.

Construction.—Locate At and $A't'$ the revolved position of the traces of AA and $A'A'$ on the fault plane. Lay off Θ (the angle between parallel and total displacement) $=$ 30° and find $A't$ as the total displacement, and tt' as the perpendicular displacement. Lay off Θ' (the angle between horizontal displacement and total displacement) $= 30°$ and find the total displacement $A'b$ and the normal displacement bc.

The scheme of lines chosen to represent planes, traces, lines, points, etc., used in this and succeeding discussion, is shown by the legend below.



Visible trace of plane with side of block.
Invisible trace of plane with side of block.
Intersection of plane within block.



Trace of plane with reference surface (strike line).
Trace of plane with surface 100 ft. below.
Projection of intersection of any planes.
Projection rotated back into reference surface.
Projection of a line—portion above reference surface is light solid line; that below is dot and dash. Dip of line theta is given by rotating same around its projection. (See Fig. 5).
A point is located by a small circle and the distance above or below reference plane by a dotted line.
Construction lines.

(To be Continued)

Condition of the Gas in Coal

In some cases the volume of gas liberated from broken coal is greater than the volume of the coal itself—that is, of the actual solid and the cellular space combined. Several theories have been proposed to account for this fact. If the inclosed gas is mechanically imprisoned in the microscopic pores of the coal, it must be under a pressure greater than that of the atmosphere; otherwise it would occupy after its escape a volume less than that of the coal. It is possible, furthermore, that there is a continual slow formation of methane by chemical decomposition of the coal, or it may be that the gas is held in a state of occlusion—that is, either dissolved molecularly or absorbed upon the inner surfaces of the cellular spaces. The gas which escapes from coal has been very often called 'occluded gas', but, as Chamberlin has made plain, the word 'occluded' has been loosely used in this connection, and the radical difference between mechanical imprisonment and true occlusion or condensation has been generally overlooked. The word 'occlusion' properly implies the condensation of a gas within a solid substance to a state approaching that of liquid or solid, either condensed upon the interior surfaces of the pores or dissolved molecularly in the solid. The Century Dictionary defines occlusion as the absorption of a gas by a metal, as of hydrogen by palladium, in which case the hydrogen is regarded as existing in a solid form as a quasi-metal. Mendeleeff states: "The capacity of certain dense metals for the absorption of hydrogen * * * is termed occlusion and presents a similar phenomenon to solution; it is based on the capacity of metals for forming unstable, easily dissociating compounds with hydrogen similar to those which salts form with water."—*Technical Paper 2, Bureau of Mines.*

Turquoise Mines of New Mexico

By John L. Cowan

Turquoise mining is one of the newest, as well as the oldest, of the mining industries carried on in North America. It was extensively practised so long ago that no legend or tradition of its beginning can be gleaned from the lore of the aboriginal tribes. Turquoise was mined in the Southwest ages before the first Americans had learned that gold, silver, iron, or copper were of possible use or value to mankind. Then the mines were closed, their location forgotten for a hundred years, and only within the last few decades were the old workings rediscovered and the mines reopened.

The major part of the civilized world now receives its supply of turquoise from the mines of New Mexico. They are said to be the richest turquoise mines in the world, and to produce some of the best stones obtainable. Yet it is little more than twenty years ago that they began to be worked on a scale of commercial importance. Prior to that time the owners of the mines of Persia, on the slopes of Mount Ali Mirza, enjoyed a practical monopoly of the trade in this beautiful semi-precious stone.

There are four important turquoise districts in New Mexico. One is the Burro mountains, southeast of Silver City; one near Los Cerillos, 16 miles from Santa Fé; one near Old Hachiti; and the fourth in the Jarilla mountains. In all these districts, turquoise was mined centuries ago by the aborigines, and in more recent times by the Spaniards. Their modern exploitation began a quarter of a century ago, when some of the old mines were rediscovered, and an impetus given to the search for new deposits; but it is only since 1890 that the production of turquoise in the United States began to assume important proportions, and that the American gem began to win a position placing it on a parity with that long held by the Oriental stone. The antiquity of turquoise mining in New Mexico is proved by the finding of many stones when excavations are made among the prehistoric cliff dwellings, as well as by the ramifications of the mines at Mount Chalchihuitl and in the Burro mountains. So extensive are these workings that it has been argued that their origin must be attributed to the Spaniards. This is claimed on the ground that the aborigines, ignorant as they undoubtedly were of the use of metals, could not possibly have performed work of such magnitude. However, in the old workings and dumps have been found great quantities of relics of the Stone Age that seem to establish the antiquity of the mines beyond the possibility of doubt. Among these relics are rude stone hammers and hundreds of fragments of pottery of the most ancient of known types.

It is now generally believed that the large quantities of turquoise found by the Spaniards in the possession of the inhabitants of Mexico at the time of the Conquest had been obtained from the mines of Mount Chalchihuitl and the Burro mountains. This stone was highly esteemed by the ancient Mexicans for use in mosaic and inlaid work. With it the famous gold throne of the Tezones was inlaid and ornamented. Like their modern descendants, the ancient Pueblo and other aboriginal tribes used the gems both for purposes of personal adornment and as a medium of exchange.

Some of the most valuable specimens of ancient Mexican (or Aztec) work in this material have found their way to famous European museums. Among these is a portion of a human skull bedecked with pieces of turquoise and other gems, the design imitating war-paint decorations upon a human face. A favorite embellishment of ancient Aztec idols was a somewhat similar design, in which the turquoise was prominently used. Probably the oldest mines are those of Mount Chalchihuitl (the Indian name for turquoise), near Los Cerillos, about fifteen or sixteen miles from Santa Fé. The 'mountain' is really no more than a moderate-sized hill, of a white and yellow rock that makes it a conspicuous feature of the landscape. These mines were also worked extensively by the Spaniards after their conquest of the territory. It is claimed that about the year 1679 or 1680 twenty Indians of those compelled to work in the mines were killed by a caving in of the workings, and that this was one of the principal causes of the general revolt of the Pueblo tribes that drove the Spaniards temporarily from New Mexico. This is the earliest recorded mine disaster within the present limits of the United States.

Considerable development work was done on Mount Chalchihuitl a few years ago, when the old workings were thoroughly explored and every endeavor made to discover a continuation of the gem-bearing deposits. The money and labor thus expended returned no adequate results, it appearing that the deposits of gem material had been exhausted. Three miles northeast is another mine that was also worked by the Spaniards, and was rediscovered in 1885. In the immediate neighborhood are the extensive mines controlled by Tiffany & Co. of New York; probably the greatest turquoise mines in the world. The production of the Tiffany mines is purposely kept at a low point in order to avoid depressing the price of the gems. For this purpose, the mines are now closed down indefinitely. Great trouble has been experienced at these properties by the refusal of the San Domingo Indians to respect the property rights of the New York company. The Indians argue that they and their ancestors owned and worked the mines long before a white man ever set foot in America; and they fail to see by what right the interloping Americans claim exclusive possession now. Large quantities of turquoise have been surreptitiously mined by the Indians every year, and at times the neighborhood has been made decidedly dangerous for the Tiffany manager. The Indians dispose of the gems thus obtained to tourists and to filigree jewelry makers in Albuquerque, Santa Fé, and other towns.

The turquoise mines of the Burro mountains were also worked by the aborigines, but not so extensively as those of Mount Chalchihuitl. Here stone hammers, fragments of pottery, and similar relics of prehistoric times have also been found in the workings and dumps. The modern discoverer of these mines was John E. Coleman, better known throughout the territory as 'Turquoise John', who located a number of claims in 1879. The next year M. W. Porterfield, Nicholas C. Rascom, and T. S. Parker located claims that have been extensively developed. In the quality of the gems produced, and in the quantity that could be mined if the demand justified, the Porterfield properties are believed by many to rank with those controlled by Tiffany & Co. Turquoise was discovered in the Jarilla mountains in 1898. The most important of the claims is known as the De Meules property, named after its discoverer, Amos De Meules, of El Paso. Since the death of De Meules, the mines have not been worked, although some magnificent gems have been discovered near the surface. In the Old Hachiti, or Eureka, district, turquoise of fine quality is mined in a desultory fashion, but systematic exploitation has not been attempted. In the neighborhood of both the De Meules and the Old Hachiti properties there is abundant evidence of extensive mining operations in prehistoric times.

The geological conditions under which turquoise is found vary so widely that no general statement is possible. In the Los Cerillos district it occurs in a red trachytic rock. In the Burro mountains it is found in a decomposed feldspathic granite. In Nevada it is found in a metamorphic sandstone. At the foot of Mount Sinai a worthless turquoise occurs in a red sandstone. Other localities in which it is found under still different conditions are on the slopes of the Mount of the Holy Cross in Colorado; in Fresno county, California; in Alabama, Arizona, and Chile. The modes of occurrence on Mount Ali Mirza and in the Burro mountains are very similar; and chemical analyses of the turquoise from these two widely separated regions are practically identical. This seems to indicate that the conditions there found are best adapted to the production of the perfect gem. The principal coloring constituent of turquoise is a compound of copper.

Many attempts have been made to explain how the aborigines were able to carry forward their extensive turquoise mining operations with the crude implements at their disposal. Perhaps the most plausible explanation is that given by M. W. Porterfield, of Silver City, New Mexico. He says: "The frequent occurrence of charcoal in the old workings leads to the belief that the mining was accomplished by first heating the rock and then pouring water upon the heated surface, causing it to crack. Then stone hammers were brought into requisition to separate the matrix from the true turquoise. This process must have been very slow, and the amount of work accomplished in the mines must have taken centuries of ceaseless, patient toil for its completion. Measured by our valuation of time and labor, the gems thus extracted would have been worth hundreds of dollars per carat. Even with all our modern conveniences and improvements for mining, it requires special skill and extreme care to take out turquoise without destroying more than is recovered. The quick action of giant powder is not considered as satisfactory as the slower effects of black powder; and even the 'water blast', as employed by the aborigines, would, in some cases, be more economical."

Although the Spaniards, after the conquest of New Mexico, worked some of the turquoise mines extensively, the general industrial eclipse that fell over the whole Southwest in the decadent later days of the Spanish occupation led to their abandonment. The exquisite polish of some of the gems dug from ancient burial places, and the extreme delicacy of the perforations made to permit them to be strung, have often excited the astonishment of modern lapidaries. The usual work of the aborigines is crude in comparison with that of workmen having all the tools and appliances of civilization, and that they performed such work with only the crude tools and appliances of the Stone Age is difficult to believe. Hence, it is sometimes suggested that the Southwest has its lost arts as well as the ancient civilizations of Africa and Asia.

Statistics of 1910 Copper Production

Hayden, Stone & Co. report that the thirty principal producers of copper in this country produced last year 937,948,000 lb. of copper, for which they received $118,417,000, or 12.6c. per pound. The cost of this production was $85,680,000, and the profit $32,737,000. In other words, these companies made a profit on their operation of a little less than 40%. Considering that this production represents the liquidation of so much wealth, this is very modest. It is interesting to observe that a lower price for the metal was met by generally decreased costs, the average cost of the whole production being just a shade over 9c. per pound, showing considerable improvement in this respect over the 1909 figures.

It is noteworthy, however, that four of the companies—Calumet & Hecla, Nevada Consolidated, Phelps-Dodge, and Utah Copper—with a combined production of 359,000,000 lb., or a little more than one-third of the total, earned $17,500,000, or considerably more than one-half of the total net earnings. Outside of these four companies the cost of the rest of the production, 578,000,000 lb., was just about 10c. per pound. Five companies, with a total output of 22,500,000 lb., produced their copper at a loss. Taking the year's record as a whole, it was one that reflects much credit on the managements, but from the investor's standpoint, it is unsatisfactory, as the net return was not sufficient to both reimburse the depreciation of principal and justify the risk.

Next to Pennsylvania, West Virginia possesses larger supplies of coking coal and other high-grade coals than any other State in the Union, but so long as both the coal and the coke continue to be shipped out of the State, West Virginia will not attain the position she should occupy as a manufacturing State, nor will the miners of coal and makers of coke receive a just return for these products.

The Rand Gold-Mining Industry and its Future

By F. H. Hatch

(Continued from page 98.)

In the past the use of machine-drills for stoping has not been looked upon with much favor. For this there are several reasons: first, the machine used was the heavy drill employed for development work, and with this type it was impossible to work in narrow stopes without breaking a large amount of waste; secondly, the bands of barren quartzite, with which the conglomerate is often interstratified, suffered such pulverization by reason of the large blasting charges used, that often it could not afterward be eliminated by sorting; and thirdly, the large blasting charges were found to weaken the roof, so that a greater number of pillars had to be left for its support than was the case with hand-drilling.

Only in wide stopes, on a large homogeneous reef with good walls, could these drills be used to economic advantage. The necessity for a good stoping drill for narrow reefs, however, has become more and more pressing with the extension of the mining industry, with which the supply of native labor for hand-drilling has not kept pace. In consequence the Chamber of Mines decided, in the beginning of 1908, to offer a prize of £2500 for the best small drilling-machine that could be produced for mine work on the Witwatersrand. The prize money was subsequently raised to £5000 by the offer of the Transvaal Government to subscribe an equal amount. A committee was appointed and a series of competitive trials took place during the year 1909, the report of the committee being published in 1910. The width of the stopes in which the competition was held varied from 24 to 45 in.,[1] and the results showed that it was possible to break ground as cheaply in narrow stopes with small machines, as by hand. The winning machines were of the reciprocating percussive type, thus reversing the result of a previous competition, held in January 1908, at the instance of the *South African Mines*, when the first place in the competition was won by a hammer-drill. The names of the four leading drills among the competitors are given in the following table, together with the footage drilled by each, the average drilling speed over the total time, and the cost of driling per foot.[2]

TABLE SHOWING THE RESULT OF THE STOPE-DRILL COMPETITION OF 1909

Machine.	Footage Drilled.	Average Drilling Speed (in. per min.).	Cost per Foot Drilled (pence).
Holman $2\frac{1}{8}$-in.	12,779	0.742	9.77
Siskol	14,083	0.818	9.90
Holman $2\frac{3}{4}$-in.	11,744	0.682	10.91
Chersen	11,781	0.684	11.94

These costs compare favorably with the cost of hand-drilling, which is rarely less than 13 pence per foot drilled. The tonnage broken is as 6 to 5 in favor of the machines, while the cost of explosive is as 6 to 5 in favor of native labor. Since the cost of native labor tends to increase, and this item amounts to 3d. per foot drilled in machine-drilling, as against 10d. per foot drilled in hand-drilling, this is also in favor of machine-drilling. It therefore may be taken as established by this competition that machine-drilling in moderately narrow stopes costs no more, and perhaps even less, than hand-drilling by natives. Hundreds of small drills (drilling a hole to take a $\frac{7}{8}$-in. explosive) are already employed for stoping on the Rand,[3] and their average duty is $\frac{3}{4}$ fathom per shift. To stope very narrow and low-grade reefs, hand labor is still necessary; but it is hoped that a drill capable of doing even this class of work will eventually be evolved.

The removal of the gold-bearing conglomerate bed which, except for its somewhat steeper dip, may be compared to a coal-seam, leaves an open space, which is not allowed to fall in, as in a coal mine worked on the long-wall retreating system, but is supported over enormous areas by pillars of unworked conglomerate in the stopes; by ribs left above and below drifts; and by pillars left to ensure the safety of the shafts, supplemented in some cases by filling with waste rock. These methods have sufficed in the past to keep open the stopes and drifts and to protect the shafts; but, owing to the robbing of the stope pillars in the outcrop mines, and more especially to the increased pressure of the superincumbent rock mass in the deep levels, serious movements of the hanging wall have lately been making themselves felt, crushing the pillars in the stopes, destroying the ribs above and below the drifts, and in some cases even affecting the shaft pillars.

HAND-DRILL WORK ON THE RAND.

To arrest this untoward movement, which at one time threatened the loss of the main thoroughfares of some of the mines,[4] a system of sand-filling has been adopted. By this system the abandoned stopes and other working places in the mines are filled with sand, taken from the residue dumps or run in direct from the mill. This method has been borrowed from the Silesian coalfield, where it has for many years been in successful operation, enabling a thick seam of coal to be safely mined under towns, villages, rivers, and main lines of railway.[5]

The method employed, in the case of the old residue-dumps, is to mix the sand with sufficient water to cause it to flow down pipes in the shafts and be discharged in the stopes prepared for its reception. Where tailing is used it is pumped as a pulp from the sand treatment vats, and is thickened in cone-classifiers, before delivery underground. The pulp is conducted in wooden underground launders to the stope to be filled. Barricades are used to keep the sand in place, but it drains well, and soon packs solid enough to bear the weight of a man. The effluent water is pumped back to the surface, and this charge is one of the chief items of expense. Another is the renewal of the pipes used to convey the sand down the shafts. The sand is extraordinarily abrasive, and the life of the pipes is very short. The cost of the process is, however, balanced to some extent by the increased ore reserve due to the advantage of not having to leave pillars in the stopes, coupled with the saving of the cost of cutting them.

---

*Abstract of the James Forrest Lecture for 1911, delivered before the Institution of Civil Engineers.

[1] Forty-three per cent of the work was done in stopes of under 40 in.; but the size of the stopes depended, of course, on the local mining conditions, and not on the capabilities of the drill.

[2] The first and second prizes of £4000 and £1000, respectively, were divided between the Holman $2\frac{1}{8}$-in. and the Siskol.

[3] According to the Crown Mines report for the year 1910 (chairman's speech), $23\frac{1}{2}$% of the fathomage stoped in the early part of that year was broken with small machine-drills. Again, 20% of the total tonnage mined in the Robinson Deep is broken by small drills.—Superintending engineer's report of June 11, 1910.

[4] See chairman's speech at annual meeting of the Ferreira Deep Co., held December 14, 1910.

[5] It was first introduced at the Myslowitz colliery in Upper Silesia.

At first it was feared that the cyanide remaining in the sand would be dangerous to the miners; but a little research has eliminated this source of danger. The percentage of moisture in the pulp, as it comes from the thickening cones, is 12. It consists of water containing up to 0.02% of cyanide. By adding a 5% solution of permanganate of potash, or of chloride of lime, it is found that the percentage of cyanide in the moisture of the sand can be reduced to less than 0.0025. The effluent water from the sand-packs underground shows no trace of cyanide, and no hydrochloric acid has been found in the air of the stopes which are being filled.[6] The filling of the worked-out stopes will also assist ventilation, since it will prevent the dissipation of the fresh air current. The system is already in use at the Village Deep, Village Main Reef, Ferreira Deep, Robinson, and Simmer & Jack mines, and there is little doubt but that it will be universally adopted.

One of the most remarkable economic changes on the Rand is now being brought about by the concentration of the steam plant at two or three centres, from which power is distributed to the mines by electric transmission, or in the form of compressed air. This has largely been the work of the Victoria Falls & Transvaal Power Co., although one or two of the mining groups (notably the Farrar and the Robinson) have established their own power-stations. Electrically transmitted power is rapidly supplanting independent steam power for mills, hoisting, sinking engines, underground hoists, and pumps, owing to the low rate at which it can be purchased from the power company. The price has been fixed by agreement at 0.561 pence per unit until October 1912, and thereafter at 0.525 pence. The company has already in operation three central generating stations, namely, at Rosherville (50,000 kw.), at Simmer Pan (18,000 kw.), and at Brakpan (9000 kw.); and a fourth station is in course of erection at Vereeniging (20,000 kw.).[7] At all these stations the power is generated by steam turbines. Transmission is effected both by overhead lines (at 40,000 volts along the Rand, and at 80,000 volts from Vereeniging, a distance of 30 miles) and by underground cables (at 20,000 volts). The length of the overhead lines, including Vereeniging, is 150 miles; that of the underground cables, 35 miles. A part of the power, supplied by the company, is in the form of compressed air for rock-drills. For this, there is a supplementary station at Rosherville, generating 16,000 hp. by four compressors driven by steam turbines, and an electrically operated station at the Robinson Central Deep mine, delivering 24,000 hp. from six compressors. The compressed air is conveyed through 20 miles of air-mains, ranging in diameter from 26 to 9 in., the pressure of supply being 120 lb. per square inch.

A considerable economy will be effected by this centralization of power-generation, and the consequent reduction in the number of independent steam-plants. From the price per unit at which the Victoria Falls & Transvaal company is supplying power, the cost of a horse-power per annum, utilized continuously day and night, can be calculated: it works out at £14. It is not so easy to arrive at the average cost of a horse-power year on the mines prior to electrification, but it is stated to have been £28. In any case, the saving due to the substitution of electric motive power for steam power is undoubted, and there is, moreover, the indirect advantage of greater flexibility and more perfect control.

The introduction of electric hoists on the Rand has practically decided the long-debated question of hoisting from great depths, in favor of stage-hoisting, as against single lift. By the adoption of a large unit of load and a suitable arrangement of loading bins, the loss due to the repeated handling of the ore can be reduced to a minimum. In the new 7-compartment shaft of the Crown mines the ore is to be raised in 8-ton skips; and even greater units have been adopted at Kimberley (as, for instance, at the Wesselton, Bulfontein, and Dutoitspan mines), where 11-ton skips are in use. Underground electric hoists, to serve the inclines from the bottom of the vertical shafts, are being installed in several mines (as, for instance, at the Catlin and Howard shafts of the Jupiter mine). They will also be employed for hoisting in the deeper vertical shafts, when the depth reached is beyond the economic limit of a single lift.

Since the discovery of the Rand in 1886 to the end of 1910, 155 million tons of ore have been milled and gold produced to the value of £276,000,000, this being an average of 35.6s., or 8.4 dwt. of fine gold per ton milled. During the same period dividends amounting to £72,416,550 have been distributed, equivalent to 9.3s. per ton milled. During 1910 gold to the value of close on £31,000,000 was produced by crushing 21,500,000 tons of ore; this is equivalent to an average yield of 28s. 6d., or 6.7 dwt. of fine gold per ton milled. The working costs averaged (from the returns of 56 companies) 17s. 7d. per ton, giving an average profit of 10s. 9d. per ton milled.

As examples of large producers working at a low cost and making a good profit, I have selected the following companies, and have averaged their returns for the first three months of the present year.

Average Working Costs and Profits of some Witwatersrand Mines During the First Quarter of 1911.

Company.	Crushed Monthly (tons).	Yield (dwt. per ton).	Working Cost (shillings per ton).	Profit (shillings per ton).
Robinson	48,900	10.9	13.9	31.9
New Primrose	24,740	7.0	14.8	14.9
Simmer & Jack	68,530	6.3	12.1	14.4
East Rand Proprietary	182,170	5.9	15.2	9.6
Witwatersrand	34,860	5.0	12.6	8.4
Knight's Deep	57,820	4.7	11.7	8.4
Glencairn	18,520	3.7	13.7	1.8

These seven companies, crushing nearly one-quarter of the whole tonnage, are working at an average cost of 13.8s. This very remarkable result has been brought about by increasing, to their economic limit, the size of the units used in the various operations, such as cars, stamps, tube-mills, vats, pumps; by simplifying the methods of handling ore; and by replacing, so far as it is economy to do so, hand labor by mechanical appliances. Larger units of development[8] and the centralization of power-plant have also contributed to this result; while the amalgamation of the properties into larger units has helped to lower working costs, by permitting a reorganization of the transport and hoisting arrangements, and by reducing the standing charges.'

Working at a cost of 13.8s. per ton means that the cost of development, extraction, and reduction, including administration, is covered by a recovery of 3¼ dwt. of fine gold per ton. On 5-dwt. ore, therefore, this would allow a profit of nearly 7s. 6d. per ton. And it is only necessary to look at the value of the ore reserve of many of the big mines given in the latest published official reports to see that this is not far from the average grade of much of the ore which the controlling engineers propose to work in the near future. Thirty-six mines have blocked out ore reserves, amounting to over 69 million tons, and the value of these ranges from 11 to 4 dwt., the average over the whole tonnage being 6.8 dwt. In addition there are 12 million tons of low-grade ore developed, averaging 3.2 dwt. If this low-grade ore is included in the ore reserve, the total becomes 81 million tons, having an average value of 6.3 dwt. It is clear that over a considerable area of the Rand the average grade of the orebodies is not much above 5 dwt.[9] The inclusion of large tonnages of relatively poor reef, which formerly were considered outside the range of profitable mining, has been made possible by lower operating costs. The grade of the ore crushed has fallen in consequence. This does not necessarily imply that the increased depth of the mines has of itself caused a falling off in the actual value of the ore deposit considered as a whole. I have not been able, with the material at my disposal, to come to any definite conclusion on this point; but I am inclined to the view that a gradual impoverishment with depth does exist. It would be quite possible from existing records and assay plans to settle this really vital question; but hitherto no figures relating thereto have ever been published by any of the big houses.

---

[6] E. Pam. 'Sand-filling on the Witwatersrand.' *Jour. Chem. Met. & Min. Soc., S. A.*, 1910, p. 76.

[7] Besides the above, stations have also been erected by the Farrar and Robinson groups at Kleinfontein (6000 kw.) East Rand Proprietary mines, and at Randfontein (20,000 kilowatts).

[8] According to the consulting engineer's report for the year 1910, the Modder B. mine is being opened out in blocks of 800 by 1000 feet.

The effect of this increased tonnage and diminished grade on the life of the Rand goldfield as a whole is an interesting subject for speculation. Some few years ago T. H. Leggett and myself set ourselves the task of estimating the production of gold to be expected from the Main Reef series, if worked down to a vertical depth of 6000 ft.[10] Up to that date (1902) the Rand had already produced gold to the value of £76,800,000, and we calculated that another £1,233,500,000 could be produced down to the depth stated. The average of the figures for gold recovery used in our estimate was 38s. per ton. The actual recovery at the time averaged 42s. It has since fallen to 28s. 6d. But, on the other hand, large bodies of ore are now being worked that were then passed over as unprofitable. No doubt, to a large extent, the one factor cancels the other; so that, for the purpose of a rough estimate, as this must of necessity be, we may still make use of the sum total then arrived at.

Between the years 1902 and 1911 the Rand has produced £187,000,000. Deducting this figure from the total, there remains £1,046,000,000, which, on the basis of an average output of £30,000,000 per annum, is equivalent to a life of 35 years, that is, down to a vertical depth of 6000 ft. But, if at still greater depths the banket should contain sufficient gold to yield a profit, after deducting the cost of working (which, under the best conditions existing at the present time, is 12s. 6d. or about 3 dwt. of fine gold per ton), we may rest assured that it will be worked. What then are the limiting factors? They are generally considered to be (1) the mechanical difficulty of raising the ore to the surface from such great depths, and (2) the effect of the temperature gradient. With regard to the mechanical question the electrical transmission of power applied to stage-hoisting has so modified the mining engineer's conception of the depth from which deep hoisting is practicable, that it is now generally assumed that there are no mechanical difficulties that cannot be overcome if it pays to do so. In respect to the temperature question, Mr. Marriott's careful experiments have shown that the rise is only 1° F. for every 208 ft. of depth, and that the average rock temperature at 1000 ft. is 68.7 F.[11] Figuring on these data, the rock temperature at 7000 ft. would be only 97.5° F., and with efficient ventilation the air temperature would of course be considerably lower. It follows, therefore, that for all practical purposes the whole question turns solely on the gold content; and what may be at a vertical depth of 7000 or 8000 ft. no one can tell. This much, however, may be said: the geologic structure clearly indicates the continuance of the conglomerate or banket beds to still greater depths than even 7000 or 8000 ft., before the bottom of the great synclinal basin of the Witwatersrand is reached; and, beyond that point, the beds must still continue until they rise to form the southern lip of the basin, known to exist beyond the Vaal river.

---

[9] Compare H. H. Webb: Report to the Consolidated Gold Fields Co. for 1910: "I think this value of about 5 dwt. is a grade which will eventually represent an average over a large area of the Rand, especially in the deeper sections."

The Corrosion of Aluminum

The use of aluminum has been urged for many purposes, but the early belief that the metal was non-corrodible has proved in practice to have been mistaken. In view of the increasing use of this metal, tests recently made by E. Heyn and O. Bauer upon about 50 corroded aluminum vessels, most of which had been stored but not used, are of much interest. The vessels had been prepared from sheet aluminum in much the same way as in the manufacture of vessels from sheet iron, and all had been more or less cold rolled. After pickling, some were coated with lacquer and others sold without it. After an exhaustive study, the following conclusions were reached: (1) When aluminum is attacked by water and aqueous solutions there are two different ways in which the metal may corrode: (a) the whole surface is attacked and the aluminum is transformed into $Al(OH)_3$; (b) the corrosion is localized, accompanied by blistering and scaling, and considerable damage results, although but little aluminum may be changed to $Al(OH)_3$. (2) The nature of the attack depends upon: (A) the nature of the aluminum. The greater the cold rolling, the greater the tendency to be attacked according to type (b). If the effect of cold rolling is removed by heating at 450°, then there is no more tendency to corrode in this way, and the corrosion is according to type (a), which is not so serious. (B) The nature of the water or solution. Corrosion of type (b) never takes place with pure (distilled) water, but only with tap water which contains dissolved salts. (3) A solution which causes strong corrosion of type (a) does not necessarily cause any corrosion of type (b), and similarly, other solutions have little tendency to cause the (a) corrosion but give strong corrosion of the (b) type. (4) The vessels examined were all corroded according to the (b) type. (5) In many cases the blisters and scales occurred in lines coincident with the direction of rolling the sheets. (6) Chemical analysis showed the corroded metal to consist of $Al(OH)_3$, some CaO and some SiO_2 also being present. These last two constituents were always found in the efflorescence on metal which was artificially corroded by tap water or similar solutions. From these facts it is clear that the corrosion on the stored vessels was not due to deposition of moisture from the atmosphere, and experiments showed that atmospheric moisture attacked aluminum only according to type (a). Presumably, the vessels had been rinsed with tap water and not dried thoroughly before storage. (7) There was no difference in chemical composition between articles that corroded and those that did not. Corrosion could not, therefore, be traced to the presence of impurity in the metal. (8) Greasing with vaseline or similar substances tends to prevent corrosion of the (b) type. (9) Annealing the metal at 400 to 450°, after the cold rolling, may be advisable. This, however, makes the metal softer, so that it may be better to lessen the extent of cold rolling. (10) The utensils should be stored dry.

Electro-Plating Battery Plates

By J. D. Hubbard

Copper plates for battery aprons, when first put in place, are usually plated with from two to three ounces of silver per square foot of surface. They then readily take a coating of quicksilver and form the best medium for good amalgamation. But, whether silvered or not, mill plates do not remain indefinitely in good condition. The chemical composition of the battery water, quality of quicksilver used, size and condition of pulp passing over, and, most important of all, the particular 'dope' used by the amalgamator in dressing the plates, all have a tendency to shorten the life of an otherwise perfectly good plate. 'Brushing up' with a strong cyanide solution is the last word in poor amalgamation practice. Every time I come across an amalgamator using cyanide on his plates, or in his batteries, I ask him why he uses it, hoping some day to acquire the occult reason. But the invariable answer is, "Cyanide cuts grease."

Grease can be kept off apron plates by a little care and attention to the source of the trouble. And if any grease should unavoidably get on the plates it may readily be removed with a lye solution, or by scrubbing the spot with hot water and alkali soap. 'Scrubbing' is used in its most literal sense. Every particle of amalgam should be moved slightly every time the plates are brushed, and this cannot be done with a feather duster. A lack of energy will cause hard scales of amalgam to form, which spread and get worse with age, and are in many cases almost impossible to remove by subsequent annealing. When they commence to form and spread, the copper plate should be taken in hand at once.

Potassium cyanide is a penetrating alkali, and if used intermittently on amalgamated copper plates, will gradually form double cyanides of mercury and copper, causing the copper to 'rust', or form verdigris, which will in turn lift amalgam and even silver plating, and cause it to scale off the plate. All millmen know the bane of hard and oxidized copper plates. The hardening is due principally to absorption, and the oxidizing to deleterious chemical action. In time the plates get so bad that it is impossible to make amalgam hold to them. Mercuric chloride, or sodium or zinc amalgam offer but temporary relief. The copper plate simply gets worse. It is obvious that something must be done. A simple remedy at small and isolated mills, is to take off the copper plates, scrape them well, then heat them to dull redness over an open fire, and plunge in cold water to anneal them. The irregularities in the plate may be removed by placing them on a smooth, level surface, and hammering with wooden block and mallet. No furnace is necessary; just an open fire. Have only sufficient fire to heat the plate well. It is best to cover the plate with light dry wood, and when this has burned away the plate is ready to be plunged. This must be done as quickly and evenly as possible. Slow cooling is of no use in softening copper. There is no danger of melting or burning a copper plate of $^1/_{16}$-in. diameter or more, over an open fire. And after plunging the hot plate in cold water, it can be easily bent. After hammering out the bends and inequalities with a wooden block and scouring with fine sand, the plate is ready for use again, and should last a year or more, provided it is kept free of cyanide or acid solutions.

In many cases, where silver plating is desired, it is best to send the plates to a regular plating works, where facilities for doing a proper and thorough plating are at hand. But all large mining companies, more or less isolated, should have their own silver-plating plant. The first cost is insignificant, the space taken up is small, and the results are satisfactory. The main cost is the silver itself, practically all of which goes where it will do the most good: on the copper plates. The Oriental Consolidated Mining Co., operating at Unsan, Korea, installed a small silver-plating plant about three years ago. This company has a little over 2100 sq. ft. of copper-plate surface in use in the five mills. All the copper plates in poor condition were silver plated at this time, but without first annealing them. They gave good service for a time, but soon the plating commenced to scale off the hard plates. This finally got so bad that it was necessary to replate them. Recently the mill plates were properly annealed, rolled, scoured, and plated, and have been giving excellent satisfaction ever since.

The silver plating plant consists of two tanks and one vat (with apologies to 'KCN' *et al.*) made of wood. Metal tanks, unless heavily enameled, will not do, on account of their electric conductivity. One tank is used for stock solution, and one for rinsing the finished plate, while the middle vat holds the anodes and cathodes for the plating proper. The plating vat is made of 2-in. seasoned plank, well fitted, properly caulked, and painted with three coats of paraffine paint. The inside dimensions are: width 15 in., length 5 ft., and depth 6 ft. A hardwood cap, 4 by 4 in., is fitted across the middle lengthwise on the top of the plating vat, and $1\frac{1}{4}$-in. holes drilled every 6 in. for the wires to hold the anodes. Nine pure silver anodes 4 ft. long, 5 in. wide, and $^3/_8$ in. thick, weighing from 20 to 22 lb., are hung on these connections, and the whole connected with the main circuit. The two copper plates are lowered into the vat on either side of the anodes, and held in position against the wall of the plating vat by strips of wood. The copper plate or cathode connections are wired in a Y shape, each horn of the Y to connect each cathode or copper plate. The plating vat has a cover to lock on, to prevent an inopportune confiscation of the silver anode by the natives.

TARACOL HEAD-FRAME.

Care must be taken that there are no short circuits, and then the main circuit is closed with a switch conveniently placed near the plating dynamo. The original plates were 4 ft. 8 in. wide by 10 ft. long, in one piece. These plates cut into two sections were just the right size to go into the plating vat. The plates are first taken up and well scraped with chisels and scrapers to remove all the amalgam and scales. After cutting in two sections, holes are drilled for screws to fasten them back on the aprons, and two $^1/_2$-in. holes are made in opposite corners for the anode connections. These holes are covered with a wooden strip when put back on the aprons, and therefore do not interfere with the flow of pulp, or amalgam. After drilling, the plates are heated over an open wood fire to a dull redness and then plunged into a flat box of cold water.

At the Oriental Con. M. Co. shops there are no regular plate rolls, but a good set of bending rolls. These were adjusted to the right feed and a $^3/_4$-in. iron plate slipped between them. On this the annealed copper plate was laid and put through the rolls two or three times, taking out all the inequalities. The plates are well scoured with fine sand, and the back of each plate painted with paraffine paint to prevent plating on that side also. When the paint is dry each plate is weighed on a platform scale and the weight recorded. Two copper plates are lowered into the plating vat on either side of the anodes, and the current turned on. A dynamo made especially for the deposition of metals, manufactured by the Eddy Electrical Corporation, of Windsor, Conn., and of type I C, size I, speed 900, 5 volts, and 300 amperes, is used. The current was found to be too strong, but this was remedied by introducing more resistance in the circuit.

The copper plates are plated for 3½ hr., then turned end for end and plated for 3½ hr. more. As the plates were 5 ft. long and the anodes but 4 ft., it was necessary to turn the plates. The current, of high amperage, has a tendency toward excessive action near the surface of the plating solution, and deposits soft silver on the top part of the copper plate. If this soft or 'burned silver' is not removed with a brush, the final appearance of the plate is rough and dark where the excess silver was deposited. To overcome this, a whisk-broom was tied to a long handle of wood, and the plates brushed off every half hour, without removing the plates or turning off the current. After seven hours in the plating solution the plates are taken out, rinsed in clean distilled water, and then weighed again on the scales to see if the necessary amount of silver has been deposited, then removed to the mill. Under the conditions here, the seven hours' contact gave a deposition of 2½ oz. per square foot of surface.

The silver-plating stock solution of cyanide of silver is the most difficult part of the plating operation. It is very sensitive to all conditions of light, temperature, and chemical action, and to fluctuations of the current, which will cause both chemical and physical changes to take place in the solution. A weak solution of silver cyanide is a poor conductor, so it must be kept up to strength. From 1 to 2% is all right, but it must not be allowed to drop below 1%. Theoretically, the anode under current and with proper amount of free cyanogen in the stock solution, is supposed to add automatically sufficient silver to the stock solution to keep it up to full strength, but this is not always so in actual work. Strong cyanide of silver must be added to the stock solution now and then, depending upon the amount of work done, to keep it up to full strength.

A convenient way to test for silver in the cyanide solution is to evaporate carefully on a lead tray 10 c.c. of the stock solution, cupel the whole, and weigh the resulting silver button. As for testing the stock solution for free cyanogen, it may be done in the same way as for any working cyanide solution, by titrating with standard $AgNO_3$. The stock solution should show about 1% free cyanogen all the time. Another way to detect a lack or excess of free cyanogen, is to note the physical changes in the plating solution. If the silver deposited on the cathode has a hard and dark appearance, the anode plates assume a hard close-grained appearance, and are more or less coated with a slimy deposit of silver oxide, there is a lack of free cyanogen. On the other hand, an excess of free cyanogen is shown on the anodes by their very white frosted surfaces being pitted and their edges ragged, and on the cathodes by a soft, rough, and loosely deposited coat of silver which strips off under the brush or burnisher. Also a strong odor of cyanogen is noticed, mingled with an odor of ammonia in hot weather if much work is being done.

It must be understood that only pure silver is to be used for the plating solution. Standard silver is useless, as it contains copper, and copper quickly spoils the plating solution for effective work. Also, never leave the copper plates in the solution for any length of time when the current is turned off, as the free cyanogen will act upon them. If the silver stock solution becomes charged with copper it is necessary to make it up afresh. Use only distilled water, pure silver, and KCN of at least 90% strength. For the stock solution it is best and cheapest in the long run to buy good silver nitrate and dissolve it in pure water, precipitate as a chloride with NaCl, and then dissolve the silver chloride in KCN solution. Start off with a 2% silver solution, and afterward keep the strength up to at least 1% silver. Large wires must be used from the dynamo so as to offer small resistance to the current. In this case ½-in. insulated twisted cable was used. The time of contact may be determined by removing the copper plates from the plating vat and weighing them on the platform scales to determine the amount of silver deposited.

In conclusion the following points must be emphasized: (1) only pure silver anodes to be used; (2) large wires from plating dynamo to reduce resistance; (3) copper plates to be well annealed and burnished; (4) only pure water and high-grade potassium cyanide to be used in the plating vat; (5) free cyanogen to be 1% in excess in plating solution; (6) a stock silver solution of from 1 to 2 per cent.

A New Drill for Deep Holes

By George H. Gilman

*In many engineering undertakings, economical rock excavation requires the drilling of deep holes, of large diameter, to accommodate heavy charges of explosive. These holes, in current practice, range in depth from 15 to 50 ft., and from 3 to 5 in. in diameter at the bottom. They are usually drilled with ordinary rock-drills, from 3⅝ to 5½ in. cylinder diameter, with an additional derrick or tripod of wood or pipe to handle the heavy steel.

Three difficulties arise in using machines of this pattern. They are cumbersome and hard to move from one hole to another. Much time is lost in changing drill steel, since the range of feed does not exceed 2½ or 3 ft.; the deep holes are hard to keep free from mud and sludge, so that the force of the blow is partly lost by cushioning on mud instead of striking fresh rock at each stroke. The result of these handicaps is that a comparatively small proportion of the total working time is spent in actual drilling.

Two of these difficulties, those of transportation and of changing steel, have been solved by the use of churn-drills. The difficulty of cleaning the holes persists in this type, and is a considerable impediment to efficient work. With these considerations in mind, C. H. Locher, of the engineering firm of Grant, Smith & Co. & Locher, undertook about two years ago to devise a drill more rapid and efficient than any machine then available. This consists of a vertical standard or carriage, carrying a rock-drill cylinder attached to a heavy iron block, which is suspended in guides or ways over 20 ft. in length by a steel cable, which passes over a sheave and is alternately paid out or taken in, as needed, on a hoisting drum. The standard and hoist are mounted on a steel wagon-truck. A two-cylinder reversible engine provides power for the hoist and for moving the outfit from place to place, by means of a chain-drive to the axle of the rear wheels, above which the standard is mounted. The front wheels swivel to permit steering. The truck carries an air re-heater or a boiler as required, and jackscrews are provided at the rear end for taking up motion while drilling is in progress.

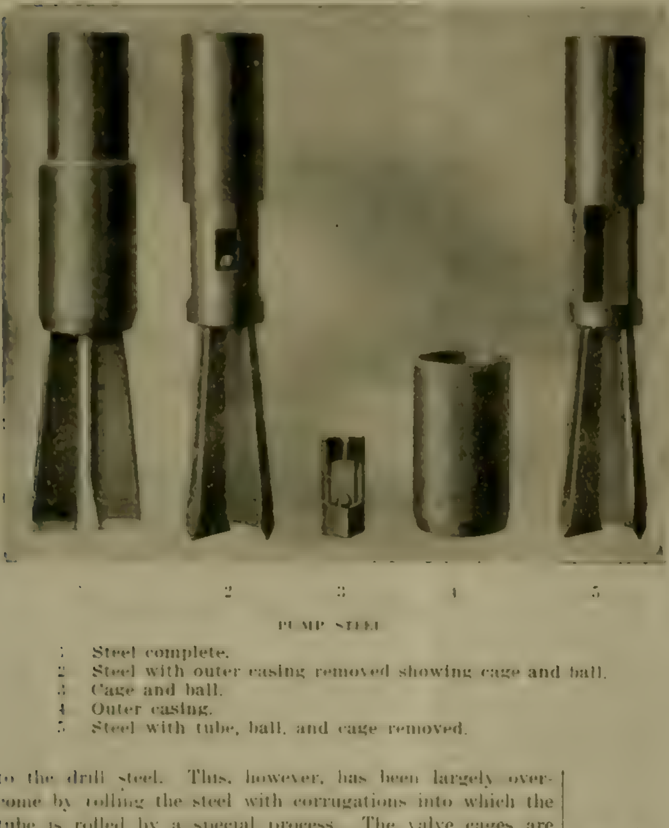
It will be seen that this outfit enables holes to be drilled to a depth of 20 ft. without change of steel. The work of cleaning the holes is accomplished by an entirely new device, which will be described before telling the nature of the performance done with this outfit or explaining its detail of construction.

When drilling in a 'blocky' formation the chief difficulty experienced with rock-drills was the extraction of cuttings from the hole as the depth increased. This was due not only to the broken condition of the ground, but seams were often intersected which led to an opening made by a previous blast, so that it was practically impossible to properly 'mud the hole'. After many devices and special kinds of steels had been tried without success, the idea of using the movement of the drill steel for direct pumping suggested itself, and upon trial gave good results. The

---

*Abstract from *Mine and Quarry*.

[illegible] employed for this purpose consists of [illegible] drill steel [illegible] a tube. The lower end of this tube is made in the form of a cage carrying [illegible] balls which act as valves. See the accompanying illustration. When the drill steel is thrown forward these balls are raised from their seats by the resistance of the [illegible] in the bottom of the hole, and a quantity of sludge is thus thrown above them. When the steel lifts, these balls are naturally dropped to their seats, thus preventing the entrapped sludge from escaping, and the rearward stroke of the drill is sufficient to throw the cuttings out of the top of the tube, where they are deflected downward by a saucer-shaped plate securely fastened to the shank of the steel.



PUMP STEEL

1. Steel complete.
2. Steel with outer casing removed showing cage and ball.
3. Cage and ball.
4. Outer casing.
5. Steel with tube, ball, and cage removed.

Difficulty was at first experienced in securing the tube to the drill steel. This, however, has been largely overcome by rolling the steel with corrugations into which the tube is rolled by a special process. The valve cages are then inserted in openings cut in the lower part of the tube directly opposite the grooves in the steel, and are held in position by an outer sleeve. With this device no difficulty was found in keeping the hole clear of cuttings, and even in broken ground little trouble was experienced in keeping the bit free.

When drilling with this arrangement, it is absolutely necessary to have a good stream of water running into the mouth of the hole. To prevent the cuttings from finding their way back into the hole, it is customary to use old sacks, held in place about the mouth of the hole by stones. To clean the hole after it has been drilled to the required depth, preparatory to loading for firing, or to regain the proper alignment in a deflected hole, it is merely necessary to throw the drill on a cushion provided for this purpose and described later. It will then reciprocate for nearly a full stroke without striking either head, and thus pump out any loose material which may remain in the hole. This system of drilling has been patented by Mr. Locher in both this and foreign countries.

The first rig was built of heavy timbers and carried a drill 5 in. in diameter, in guides providing a travel or depth of hole of 8 ft., without changing steel. This served its purpose admirably, for it demonstrated that an arrangement of this kind was practical. In drilling to the required depth, however, two changes of steel were needed for each hole, and the time required to make the changes was found to be a large percentage of the total required for each hole. It was furthermore found that by drilling larger holes a given amount of rock was broken to steam-shovel size with fewer lineal inches of drilling, and that there was a marked saving in the amount of powder used.

In spite of these handicaps, this first machine, crude as it was, worked steadily for several months, and made some interesting records. On one occasion, 29 ft. of 4-in. hole was drilled in 55 minutes, including four moves occupying about 45 seconds each. In an hour's run, with dull steel and low air pressure, 37 ft. 3 in. of hole was drilled, with five moves. In 32 minutes, three holes were drilled, 6 ft. 2 in., 7 ft. 2 in., and 7 ft. 2 in. deep, and the rig was moved three times. The first of these three holes was drilled in 5¼ minutes. Moving, from the time one hole was finished, until the next was started, occupied just two minutes.

This success led Mr. Locher to design and build another machine of more substantial construction, with a 14 ft. feed, on which was mounted a Sullivan 'UM' drill, with a 7-in. piston, capable of drilling holes to the required depth with a 5-in. bit. With this machine remarkable work was accomplished, and a drilling speed of 12 in. per minute with a bit of this size was by no means an uncommon occurrence.

In July 1910 this machine worked 28 eight-hour shifts and put in 3282 ft. of holes averaging 11 ft. in depth. This gives an average speed of 117.2 ft. per shift, of 5-in. holes, as compared with 39 ft. per shift for the 3¼-in. rock-drill drilling 3-in. holes.

The 28 shifts included 31 hours of lost time, moving away from shots, changing water lines, and other delays caused by limited space, low working-faces, etc. Seventy-five feet was drilled in 3 hours, 165 ft. in 7½ hours, and 145 ft. per day for five consecutive eight-hour shifts.

On October 26, 1910, two sets of records were taken. The first was made with a Sullivan 'UH2' 3⅝-in. drill, mounted on a gadder frame, with a small hoisting engine to raise and lower the steel, and pump steel. The leads permitted holes to be drilled 6 ft. deep without changing steel.

Hole No.	Depth (ft.).	Changing Steel (min.).	Drilling (min.).	Total (min.).
1	8	6	12	18
2	8	5	8½	13½
3	8	3½	9	12½
4	8	4	12	16
5	6	..	10	10
Total	38	18½	51½	70

Six holes were then put in by the same drill, using regular steel, and pumping the holes by hand. The regular feed-screw, 2 ft. long, was employed, so that the steel had to be changed once in 24 inches.

Hole No.	Depth (ft.).	Drilling (min.).	Total (min.).
1	8	14½	42
2	8	24	52
3	8	14	22½
4	8	18½	27½
5	8	13	32
6	6*	42	49
Total		126	225

*Bad hole.

The time for moving from hole to hole is not considered in either case. It will be noted that if the length of feed in the first record had been 8 ft. instead of 6 ft., 18½ min. would have been saved in drilling 38 ft. It will be seen from these two records that with the pump steel and long feed the rate of drilling was 1 ft. in 1.35 min.; with the regular steel and usual feed (ordinary method), 1 ft. in 4.89 min. That is, with the same labor and in the same time, the improved method accomplished 3.62 times as much work as the old or standard method.

In the summer of 1910 the work necessitated drilling holes to a depth of 20 ft. Mr. Locher decided to have a new machine built incorporating all the features which were found to be advantageous in the earlier machines. This outfit is capable of drilling holes to a depth of 50 ft. The mounting is arranged to move backward or forward at a speed of 20 ft. per minute. The hoisting speed for raising the drill and weight is 30 ft. per minute. The rig stands about 31 ft. high, is 21 ft. long, and 12 ft. wide, and weighs 33,000 pounds.

A brief description follows: The horizontal frame, built entirely from structural steel, is mounted upon four wide-tread steel wheels, those in front being swiveled for steering, while those at the rear are on a fixed axle. A drive shaft, geared direct to the engine through jaw clutches, carries two small sprockets on either side, which are connected by a sprocket chain to larger sprockets secured to the rear or driving wheels for moving the drill. Directly over the rear wheels is the vertical standard, made of channel iron, securely braced to the frame of the machine, and serving as a guide for the drill. Forward of this, mounted upon the frame, is the hoisting and propelling mechanism with its two-cylinder, reversible engine, while over the front wheels is mounted an air re-heater, through which the compressed air passes to supply both the engine and drill. It will thus be seen that the greatest weight is directly over the rear drive wheels. Jackscrews are provided at the rear of the frame, which may be set down upon the rock to give the entire machine stability in a lateral direction while drilling is in progress.

The feeding of the drill is accomplished entirely by a suspended weight, to which the drill cylinder is bolted and which provides stability. A slow retrograde movement of the hoisting drum for lowering is given by worm gearing, while the hoisting is accomplished by a train of spur gears which connect the main shaft of the engine, through a jaw clutch, with the hoisting drum. An automatic locking arrangement is provided between the hoisting drum and its gear, which prevents any possibility of the drum slipping. With the worm gear in mesh, both hoisting and lowering may be accomplished on the slow speed, while with the spur gears the drill may be hoisted only. No brakes of any description are employed, and the speed at which the various devices operate is controlled entirely by the engine throttle. The engine runs continuously while the drill is being fed at any desired speed. Every movement of the entire machine is controlled by a bank of levers so placed that each is accessible and convenient for the operator. One of these levers controls the power steering mechanism, by which the course of the rig is directed when in motion.

When starting a hole the drill steel is guided by a hinged clamp fastened to the lower end of the standard, and through which the drill-rod reciprocates. After the steel has cut to a depth slightly over the length of its stroke this clap is disengaged and swung out of the way, where it remains until the hole is finished.

A davit, with block and tackle, at the top of the standard, provides for handling the long lengths of drill steel, in connection with a winch on the main shaft of the hoisting engine.

The drill proper is an entirely new development in rock-drill practice. The cylinder is 7 in. in diameter, with a piston stroke of 8⅝ in. Important changes have been made in it to handle the heavy lengths of steel, and to secure at once speed, economy of power, and adaptability to the rock and other working conditions. It may be described as a combination of the standard drill and the chopping engine of the Sullivan direct-acting channeler, which has been in satisfactory use for many years.

The channeler valve and piston motion have been adopted to secure economy, by using the air or steam expansively. The main valve is air-thrown, but is controlled by a reverse valve mounted on the stem of a cut-off valve, which in turn is actuated by a lever in direct contact with the piston, so that the point of cut-off and the length of the stroke may be automatically regulated. Corliss valves in the exhaust ports provide a cushioning effect and prevent damage to the cylinder head in case the drill should run into a mud seam or pocket.

The usual method of rotation is employed, except that instead of boring out the piston to make provision for the rifle-bar, the rifle-bar is made a part of the piston proper by cutting the flutes upon a projection from the rear of the piston head. To eliminate cylinder wear, a guide bearing for the rod is provided by an extension from the cylinder proper, carrying a removable bronze bushing through which the piston rod reciprocates. This is one of the most valuable features about the machine, as it reduces cylinder wear to a minimum. This wear would otherwise be very pronounced when handling the long lengths of steel. The drill is lubricated by an automatic oiling device in the upper head, controlled by the pulsations of the air in the cylinder. The chamber holds about one quart of oil.

Some of the records of actual work were obtained at the crushed-stone quarry of the Church Quarry Co. at Sibley, Michigan, where it was installed temporarily, pending the resumption of the Government work at Grosse Ile this spring. At Sibley this machine has quickly drilled holes to a depth of 44 ft., and the pump-steel is entirely successful in handling sludge from holes of this depth. It is estimated that as a means for breaking ground, this outfit, run by two men, will do the work of five ordinary drills, requiring ten men for their operation, and that it will accomplish a considerable saving in powder, owing to the larger diameter of the holes drilled. The economy in motive power is also an important factor.

Australian Gold Production

The gold production of Western Australia during May was 111,028 fine ounces, valued at £471.619, as compared with 127,783 fine ounces, valued at £542.791, for the same month last year. The total for the first five months of this year has been 555,753 fine ounces, valued at £2,358,976, as compared with 608,891 fine ounces, valued at £2,586.402, for the corresponding period last year. In our issue of April 15, through an oversight, the production of the mines of Western Australia for January 1911 was given as the total for 1910. During 1910 eighteen mines in Western Australia paid dividends amounting to £1.028.393, instead of £95.700, as there stated.

The yield of the Queensland gold mines for May amounted to 37.188 fine ounces, valued at £157.964, as against 36.909 fine ounces, valued at £156.779, for the same month in 1910.

The return furnished by the Under-Secretary for Mines of New South Wales shows that the yield of that State for May was 24.389 oz. crude, equal to 21,319 oz. fine, valued at £90,558, as compared with 12,681 oz. crude, equal to 11,184 oz. fine, valued at £47.506, for the same month in 1910. The yield for the first five months of this year amounts to 89.571 oz. crude, equal to 75,310 oz. fine, valued at £319.898, as compared with 87.982 oz. crude, equal to 74.640 oz. fine, valued at £317.050, for the same period in 1910, thus showing an increase of 670 oz. fine, and £2848 in value.

The gold produced in New Zealand during May amounted to 60.371 oz. gross, or 56.557 oz. fine, valued at £240,281, as compared with 45.042 oz. gross, or 42,342 oz. fine, valued at £179.856, for the same month last year. Since January 1 the gold produced has amounted to 196.050 oz. gross, or 184.941½ oz. fine, valued at £785.581, as compared with 197.813 oz. gross, or 184.486½ oz. fine, valued at £783.648, for the corresponding five months in 1910.

Electric Furnaces

By Carl Hering

[*]The electric furnace is today no longer a laboratory device, it has taken a prominent place in the industries and has become a very important commercial apparatus, its usefulness growing steadily. Not including the very large number of small laboratory furnaces, there are today hundreds of large furnaces in use in the industries, producing thousands of tons of commercial products daily. In some cases the commodities are produced better or cheaper than before, while in others important products, which had never before been known or which could not have been made with other furnaces, are now manufactured in large quantities.

Among the present uses of the electric furnace may be mentioned the refining of steel, the reduction of iron ores by means of water power, the production of aluminum, silicon, graphite, carborundum, alundum, calcium carbide, other carbides, bisulphide of carbon, ferro-alloys, and others.

The electric furnace even promises to affect the wealth of nations. Sweden, one of whose national products for many generations was the famous Swedish iron, has for some time been losing ground in that important industry, owing to the greatly increased cost of charcoal. But owing to the enormous water-powers in that country, and the generous and wise aid of its parental government in developing them, Sweden will now be able to revive that important national industry by means of the electric furnace, which requires only a fraction of the charcoal that the blast-furnace does, and which enables the iron to be converted directly into refined steel, of considerably higher money value.

Norway's national industries will no doubt also be affected by the electric furnace. Its barren, rocky western coast, unfit for most other purposes, is admirably adapted to electric furnace industries, on account of its numerous easily available and nearly constant water-powers situated on the immediate coast where the products and raw materials can be cheaply shipped by water, which shipping will probably forever be open to normal competition and beyond the control of railroads, hence can always be relied upon to remain reasonable.

Canada and the States along the Pacific Coast, which abound in water-powers and mines, but have no cheap coal, will no doubt also be greatly benefited by the electric furnace for reducing and refining metals, provided nature's generous gift of water-power is not allowed to be monopolized by private interests, whose charges for power are governed only by the rule to charge "the highest price that the traffic will bear." The development of the electric furnace industry will depend greatly on whether or not the governments can keep control of the water-powers and regulate the charges. Existing power-plants would, no doubt, find it profitable to encourage the use of their power for furnaces, by offering reasonable and attractive rates, with an assurance of their permanency.

In its general principle, the electric furnace is an extremely simple device, as it merely converts the most available form of energy, namely, electric energy, into the lowest and most degenerate form, heat. Nature tends to do this for us if we give her an opportunity. Hence, so far as this conversion of electric energy into heat is concerned, electric furnaces require no skill to design; it is the reverse operation, namely, the conversion of heat into electrical energy, that is difficult and requires the highest skill of the engineer in the designing of boilers, engines, and dynamos, each of which itself is the result of a vast amount of study and skill.

The engineering skill required in the design and construction of electric furnaces therefore lies not in the fundamental conservation of energy, but in building them well and efficiently, the latter being of far greater importance than in combustion furnaces, in which the cost of a unit of heat is so much less that great economy is not of so much importance. Heat generated electrically costs more per unit, hence to successfully compete with the heat of combustion it must have other advantages; one of these is that such heat can be applied more directly to the materials, therefore with far less waste, and when in addition the furnace is built so as to retain the heat as much as possible, the difference in the amount of heat required may become very great, thereby compensating for the higher cost per unit.

One of the chief features in the work of the engineer, in the designing of electric furnaces, is the reduction of the loss of heat; that is, the increase of the heat efficiency of the furnace. Electric heat being much more expensive than heat from fuel, the only way it can be expected to compete successfully, as far as the cost of the heat is concerned, is by the best possible utilization of the energy; it is possible to control the losses to a far greater degree in electric than in combustion furnaces. The practice in the heat insulation of combustion furnaces would be quite inadequate for well built electric furnaces.

The reduction of the heat losses in electric furnaces, which have no chimney losses, involves the flow of heat through solids, a subject which until recently has not been given the attention which its importance demands. Heat insulation is rendered more difficult by the fact that nature has given us no virtually perfect heat insulators like those for electricity, and that even if they existed they could not be used for high temperature insulation on the outside of a furnace, as the whole furnace wall would then assume the full inside temperature, like in cases of over-insulation, which few known refractory materials would stand; and if used on the inside of a furnace it would have to withstand the chemical actions of the liquid materials and slags. Apparently the only way a high-temperature furnace can be insulated effectively with present materials is to provide for a certain allowable flow of heat through the walls, which shall be as small as possible, but not so small as to run the risk of over-insulation, which is more serious than insufficient insulation, as the walls and roof are then destroyed. It therefore requires careful designing, and there is great need of data which at present exist only in very crude form or not at all.

There are two kinds of losses of heat from the interior of an electric furnace, namely, through the walls and through the electrodes, which are subject to the control of the designer, assuming, of course, that the doors and openings of other kinds are made as few and small as possible. A few years ago I made some analytical studies of these two sources of losses, some of the conclusions of which were surprising, showing that former practice had been in some respects far from correct. The chief results are briefly as follows:

The usual formulas used for calculating the thermal resistance of such bodies as the walls of furnaces were found to be very greatly in error, as much as 100% and over, for thick walls. In general, for a flaring conductor, like one of the thick walls of a rectangular furnace, the proper mean cross-section is not the arithmetic mean between those at the two ends, but the geometric mean, that is, the square root of their product.

Using the correct formula, it was then found that the losses diminish very rapidly at first as the walls are increased in thickness, but that after the thickness has been increased to about one-half or three-fourths of the inside diameter, any further improvement in reducing the losses becomes small. The space in the inside of a furnace should be as small as possible to hold the charge, as the losses for the same charge increase rapidly with an increased inside surface. The losses in a large furnace can be made far smaller relatively to the charge than in smaller ones; hence it is considerably better to use one large furnace than two smaller ones of half the capacity.

Concerning the losses in and through the electrodes, the problem was far more involved, and former practice was in some respects found to have been radically wrong. An electrode naturally should be a good electrical conductor in order to reduce the resistance losses. But it then also is a good heat conductor and will tend to abstract considerable heat from the charge inside, thereby chilling it. Increasing its cross-section decreases one of these losses and increases the other, thereby complicating matters. The results of the analysis are briefly that, by so proportioning an electrode that the current in it will heat its inner end to the furnace temperature, the total combined losses will be the least possible, and the electrode will at the same time abstract no heat from the charge; it will then in effect act as a perfect heat insulator, better even than the walls, as far as chilling the product is concerned.

---

[*] Abstract of a paper presented at a meeting of the Electrical Section of the Franklin Institute, April 20, 1911.

Another result was that the former practice of basing the size of electrodes on certain allowable current densities was found to be entirely wrong. Still another unexpected and surprising result was that graphite with its higher heat conductivity was more economical in size and losses than carbon, and that the metals were far better than either, the best electrode material being copper, quite the contrary to what would have been supposed.

In conclusion, the following statistical data concerning existing commercial furnaces may be of interest.

The carborundum furnaces are 30 ft. long and 12 ft. wide, require 1600 kw. at 20,000 amp., 80 volts and 25 cycles, have an estimated temperature of 2300° C., and yield 15,000 lb. of crystalline carborundum at each run.

The graphite furnaces are just like these and yield about 17 tons per day, the output last year being 12,000,000 lb., of a purity up to 99.9%; the temperature is estimated to be about 4000° Centigrade.

The silicon furnaces are double electrode arc furnaces 10 ft. wide and 16 ft. long, and require about 1000 kilowatts.

The bisulphide of carbon furnace is 41 ft. high, 16 ft. in diameter, requires about 400 hp., and yields about 6 tons per day; it is a 3-phase arc furnace with three electrodes; the temperature is said to be about 1000 to 1500° C. Although built in the last century (1898), when it was probably by far the largest electric furnace ever constructed, it is running today as it was then. It is probably the most efficient electric furnace in use, as far as the economy of heat is concerned. It revolutionized the manufacture of bisulphide of carbon. The materials charged are sulphur and charcoal, and the product is a vapor which is subsequently condensed.

For the melting and refining of steel there seem to be at present nearly 100 arc furnaces in use, mostly in France and Germany, although the few in this country include the largest ones. They are chiefly the Heroult and the Girod types. They are mostly of about 300 to 800 kw., and are for charges of 2 to 5 tons; the largest ones are in South Chicago and Worcester, having a capacity of 15 tons and requiring about 2000 kw. There are also several ore-reduction arc furnaces in use and under construction on the Pacific Coast, and in Domnarfvet, Sweden, the latter producing 2500 tons per year and requiring 400 kw., or about 6500 lb. of pig iron per horse-power per year. In Norway two furnaces are under construction, each for 7500 tons annually, requiring 1850 kilowatts.

The Government of Sweden is about to make available 600,000 hp., a large part of which will be used for reducing iron. Electric-furnace reduction of iron is said to save about two-thirds of the carbon, only one ton of charcoal being used instead of three, per ton of iron. The escaping gas is three times richer, as it contains no nitrogen, and is only one-eighth in amount, hence correspondingly less heat is carried off by it. Finely powdered ore can be used without briquetting; there is less labor cost, and less cost of erection. There are 30 to 40 induction furnaces in operation, mostly in Germany. They are 200 to 500 kw.; maximum, 750. The charges are from 1½ to 5 tons; maximum, 8½ tons. In some cases the material is charged hot and in others cold. Among the pioneers to whom the present commercial furnaces are due may be mentioned Acheson, Taylor, Hall, Tone, Colby, Heroult, Girod, Keller, Kjellin, and Stassano.

The Human Factor in Accidents

By David S. Beyer

[*]A large percentage of our industrial accidents can be attributed to carelessness, indifference, willingness to take chances—the same fundamental human failings and shortcomings that are found in the office and the home as well as in the mill. Rudyard Kipling has recognized the universal nature of our human characteristics and expresses it in the following lines:

"Who shall doubt the secret hid
Under Cheops' pyramid
Is that the contractor did
Cheops out of several millions;
Or that Joseph's sudden rise
To Controller of Supplies
Was a fraud of monstrous size
On King Pharaoh's swart civilians."

I venture the further surmise that if we could dig up the tablets on which the accidents of that day were recorded, we would find that men were suffocated in the wheat bins of Egypt, just as they are in Chicago's grain elevators; and I do not doubt that if the wearing of safety goggles had been made compulsory among the stonemasons who built the pyramids, these goggles would often have been found on the foreheads instead of over the eyes they were intended to protect—just as I have seen them in a modern steel foundry.

With the development of the complex and powerful machinery which is used in our modern industries, we have added an additional and magnified element of risk that is lacking in the more simple and fundamental occupations. The man who hurriedly jostles against his neighbor in the street may do so with impunity, but it is a different matter when a steam-engine or an electric crane is substituted for the passer-by. In the steady, rythmical motion of a large machine one readily forgets the 1000 hp. of energy back of it, in comparison with which the human body is as insignificant as a pebble to the steam roller.

It is not strange that a man who has worked day after day for several years in a blast-furnace plant, without any inconvenience, should forget that the colorless, odorless gas which is present in greater or less degree at all times can deprive him of his senses, or even of his life, without any perceptible warning, if he happens to breathe too much of it. It takes a tragedy to bring this home to his consciousness, and even then the effect soon wears off.

I have in mind a plant where several men have died as a result of being overcome by gas. The most recent accident involved a man who had had several years' experience about the plant and knew of the former accidents. He was on duty in a motor-house near the gas washer. There were no gas mains or direct connections to the little building in which he was located, and the work was so light that one man could easily have taken care of it. As a special precaution, however, an extra man was always employed at night so that a single person would not be left alone where he might be overcome by gas without anyone knowing about it. One night the motors were shut down for a few hours, and these two men had some idle time on their hands. They locked the doors of their house on the inside so that they would not be disturbed, and one of them made a bed of waste back of the switchboard, lay down and went to sleep. The other one sat in a chair, but he, too, must have become drowsy and did not notice that the water had escaped from a valve outside the building and that gas was leaking in through openings in the walls. When the doors were broken open a short time after-

You may say that this is an extreme case—and so it is—but examples of similar short-sightedness are constantly coming to our attention, and I could multiply them indefi-

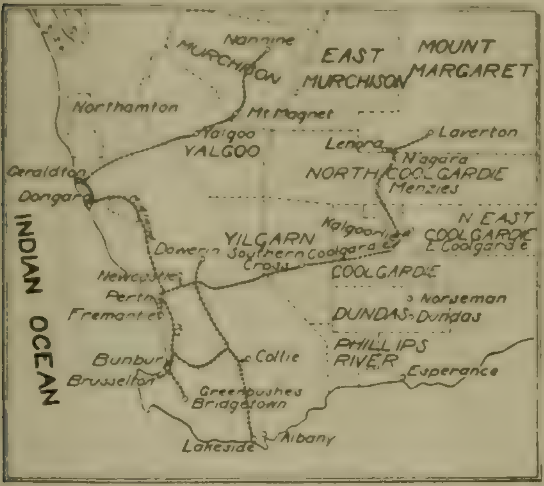
[illegible]. Frequently, as in this instance, it is the [illegible] who has to pay the penalty [illegible]. Fortunately the penalty is not often so severe as it was in the case I have described.

Scientific Prospecting

London Correspondence

An excellent example of scientific prospecting is to be found in the case of the Great Fingall gold mine, one of the Bewick Moreing group at Day Dawn, near Cue, Western Australia, not far from Mt Magnet (see map). For several years this mine gave wonderfully good results, but at a depth of 1200 ft the orebody became impoverished, though for three more levels the ore was good enough to mine. The engineers proceeded to do further prospecting at depth, and subsequently Malcolm Maclaren made a scientific examination. Prospecting was begun by sinking a winze from the thirteenth level in the foot-wall, the hanging wall being too crumbly. Just above the sixteenth level a wedge of white quartz began to appear, increasing in width until the winze was wholly within it. This white quartz was of no value. On opening out at the seventeenth level (at 2332 ft.) some dark quartz containing gold was cut on the hanging-wall side. It was 6 ft. wide, and rich. Then a drift was extended north and south, exposing similar dark quartz for a distance of 337 ft., with 14 dwt. ore in the north face. The winze is now being sunk below the eighteenth level (at 2492 ft.), where a drift has been started northward in ore.



SOUTHERN PART OF WESTERN AUSTRALIA.

This evidence does not indicate a new mine, as yet, but most assuredly it encourages further exploration and justifies the energetic policy of the management. According to Mr. Maclaren the Great Fingall vein is gold-bearing only where it crosses a dike of quartz-dolerite, which is 1200 ft. wide. This is a striking proof of the relation between ore deposition and petrography. Since the dike dips northwest, the ore-shoot pitches at an angle made by the crossing of the planes of the vein and the dike. This accords with observations in other regions. The Great Fingall vein carries two kinds of quartz, a dark variety, which owes its hue to "loss of light by total reflection from internal strain surfaces," and a white quartz of the ordinary type. The latter is younger than the former and was deposited during a renewal of the fracture marking the line of the present lode. More important is the fact that only the dark quartz is rich enough to constitute profitable ore; the white quartz is uniformly barren. The reappearance of the dark quartz is therefore significant. It reminds Mr. Maclaren of the conditions on the Champion Reef, in India, where the vein, after passing through a poor zone, became as rich at 4000 ft. as it was at the surface.

Copper for Casting

In copper for casting, certain properties are demanded, which a writer in the *Europäische Technische Korrespondenz* has given in detail. The metal is to be considered from the following standpoints: (1) Brand or source, (2) conductivity, (3) chemical composition, (4) form.

The brand has great weight in determining the value of the metal, as it gives the buyer a great deal of necessary information. In a good brand there is found, for example, a high degree of homogeneity. This is very important in a foundry where alloys are to be cast, as the 'mix' can be made according to the formula, without any anxiety as regards the result. A copper pig without any brand, or with one unknown in the foundry in question, might have the best qualities possible to obtain, and yet be less valuable than one of which definite knowledge was possessed. A good brand, however, will never risk the name of the refiner or the good qualities of the castings made from it.

The second quality, electric conductivity, might seem to one who was casting bearings or chandeliers, as of no importance; it is, however, because the greater the conductivity the purer the pig; and this is especially true in regard to arsenic. The following table shows very plainly the connection between conductivity and purity:

Percentage of arsenic.	Relative conductivity.
0.03	100
0.06	90
0.12	80
0.22	70
0.35	60
0.53	50
0.80	40

The impurities found in the pig are of two kinds—metallic and copper oxide. The latter may in one sense increase the conductivity, but at the expense of strength; the metallic impurities may increase the tensile strength in the hammered bar, but reduce the conductivity.

As regards the chemical analysis, the founder can be well satisfied if he gets 99.9% purity, even for the most particular alloys. The impurities are, for the most part, arsenic, antimony, iron, sulphur, bismuth, selenium, and tellurium.

Where the metal comes in pigs or bars partly joined to another, and which must be cut or broken apart, there is danger that the crucible will be damaged by the sharp or jagged ends resulting from the separation by cutting or breaking. Slabs and plates, on the other hand, must be cut into strips by shears, and this takes time and costs money; but the freight on slabs or plates is less than on the other forms. The founder 'pays his money and takes his choice.'

Reinforced Concrete Specifications

The investigation of the rusting of steel in concrete by the science committee of the Concrete Institute, has led to the following conclusions: The sand, stone, and cement must be thoroughly mixed and properly proportioned, and must be fairly wet and well hammered into place to minimize voids. The aggregate should pass a ¾-inch sieve and should be as non-porous as possible. The concrete covering should never be less than ¼ inch in thickness, and in the case of round bars, should be as thick as the diameter of the bar. In structures exposed to water or damp air, the thickness of the concrete should be increased at least 50%, and the size of the aggregate should be reduced to obtain a dense skin. The reinforcement must be completely surrounded by concrete, sufficient space being allowed between each piece and its neighbor for this purpose. All steel should be firmly supported during the ramming of the concrete to avoid displacement. Thick rust should be removed by scraping or by means of a steel wire brush, but the reinforcement must be neither oiled nor painted.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Threatened Rockslide in Crow's Nest District

The Editor:

Sir—The reference to the Crow's Nest Pass Coal Co., in connection with a threatened rockslide from Turtle mountain, as printed under the head of Special Correspondence, from Toronto, Canada, on page 87 of the *Mining and Scientific Press* of July 15, is incorrect and unfair to the company mentioned.

Turtle mountain is near Frank, Alberta, while the mines of the Crow's Nest Pass Coal Co. are all in British Columbia, at Michel, Coal creek, and Carbonado (Morrissey), respectively. The nearest of these places to Frank is Michel, about 27½ miles distant by rail. Even at half that distance in an air line, the nearest colliery of the Crow's Nest Pass Coal Co. is well without any danger line from threatened disaster across the Rocky Mountain divide between the provinces of British Columbia and Alberta.

E. Jacobs.

Victoria, B. C., July 19.

English as She is Writ—in Prospectuses

The Editor:

Sir—I am sending you a copy of a prospectus which I have just received, thinking it may be particularly interesting to you in connection with the discussion you have had in your paper, from time to time, regarding the relation of grammar and good English to technical writing.

R. S. Haseltine.

Oilfields, California, July 21.

[Some extracts from the prospectus follow.—Editor.]

"About one hundred and thirty feet above the Native Copper location is a strip of green grass over twenty feet wide that follows our ground the entire length. Below this contact is where all the float is found for a radius of a mile or two. Above the contact mentioned there is no float or stain. Now as there is plenty float in a small tunnel run in the hill in the slide, and away from the dreanery of the Native Copper claim but running in the direction of the contact mentioned besides finding shale and other indications at the said contact, it is our belief that there is a large contact at the above mentioned streak running through the mountain parallel with our ground, and farther, it may be and is probable that our main body of ore is at that contact. * * * If we can find what we have reasons to think we will find, there will be enough for all, and if we fail to find the ore as we think we will, it will not cripple anyone much. * * * In case we find that after we have prospected the ground to our satisfaction and find that in our opinion it is no good, we will protect our ground in all manner, and if there is any money left it is to be refunded to the stockholders per ratio as per their holdings of said stock. The elevation, about 3300 feet. Ore assays as per sack samples: Shipping ore 13.60 to 36.78 per cent copper. Gold, .82 per cent. Silver, one ounce and .20. Figuring copper at ten cents per pound which is less than market value, according to our assays our shipping ore is worth $24.60 to $70.20 per ton."

The Editor:

Sir—As many wonderful and great things come out of California, the following bit of light ought not to be hidden: "The 'country rock' so called, is not composed of a true granite but what is termed monzonyte. It consists of a mica-schist, spar quartzite and gneiss."

The 'report' went on to say that one vein carried from 9 to 58% tungstic oxide, another from 4 to 36% vanadium oxide; and "it has just been discovered that the ore carries thorium and selenium, and you, of course, know that these two minerals are in great demand." This gem was describing a silver mine, "some of the veins carry high values in silver, assaying 1000 oz. to the ton, * * * still others carry good values in lead, * * * and all carry a certain amount of gold" (a veritable embarrassment of riches). But as I have known of several 'mines' starting out, in their prospectuses, as silver-gold ones, and winding up as vanadium or tungsten properties, I was not convinced by this effusion (which calls to mind another—"a lacolithic dike of basic mud").

W. N. Cummings.

Tucson, Arizona, July 12.

Dredging Costs and Methods

The Editor:

Sir—I have been much interested in watching the dredging work in the Key Route basin in Oakland harbor, and thought that some of your readers might be familiar enough with the conditions of this or similar work in other places to give approximate working costs and details of operation. Is the method employed here one that has been proved satisfactory elsewhere, or are the contractors following new ideas? It seems to me that much of the mud lifted by the clam-shell buckets, to build the so-called retaining wall or dam must, as no bulkhead was first constructed, slide back into the excavation, also that considerable material must be lost from the sides and bottom of the buckets after they are lifted from the water and while the boom is being swung into proper dumping position.

Is the work paid for on the basis of cubic yards theoretically lifted by the buckets; estimating the yardage by the capacity of the buckets and keeping count of the buckets lifted, or are measurements made of the wall, and excavation? If the first method is employed, it would seem that a much greater quantity would be estimated as being in the dam than actually there. The rock brought in on barges and dumped on this mud wall to assist in strengthening the dam is, so far as I have seen, all small in size. For this purpose I would consider large pieces of rock and boulders far more efficacious; such as those used by the Southern Pacific when filling around their trestles and piers and by the Government when building the walls on either side of the estuary.

I understand that suction dredges will be used to fill in behind the dam, and would like to know the cost of such work; which varies, I suppose, according to distance the material is conveyed. Are dredges similar to those used in the Oroville and Folsom placer districts ever used in harbor work, and have suction dredges ever been successfully used in placer mining? Does the mud and sand in the Key Route basin carry an appreciable amount of gold? Some years ago it was claimed that the mud in parts of San Francisco bay carried as much as 25c. per cubic yard, but I believe investigation proved otherwise.

J. C.

San Francisco, July 21.

Most of the ground talc is used in the manufacture of paper of various kinds, especially building paper. It finds application also in the manufacture of molded rubber forms and as foundry facings and paints. It readily absorbs grease and is used to remove spots from silk and to bleach cotton goods. On account of its slipperiness, one of its most important properties, it is widely used to lessen friction, and for this purpose it is dusted into gloves and shoes and blown into conduits to ease the introduction of electric wires or other conductors. One of its widest applications is in toilet powders, most of which are made of high-grade talc imported from Europe. Laundry tubs, griddles, foot warmers, and many other similar utensils are manufactured from soapstone. The higher grades of massive talc, free from flaws, are sawed up to make pencils or crayons, french chalk, gas tips, and other special articles.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TO COOL hot journals apply a dressing made of 11 lb. black lead, 23 lb. epsom salts, 9 lb. sulphur, 2 lb. lamp black, and 5 lb. oxalic acid, mixed and ground together.

A ROUND FILE that has become clogged with solder or white metal filings can be easily cleaned by saturating with ordinary machine oil and holding in a flame. The heat will melt the soft metal without injuring the temper of the file.

TIN can be recovered from scrap by any one of several processes, the sodium stannate process being the most successful. Clean tin scrap can be easily treated to recover its coating of the metal, but old rusty tin cans offer a good deal of difficulty. In this country the work is, in most cases, a minor industry of the large smelting companies.

A GLUE that resists the action of hot and cold water and the majority of the alkalis and acids is composed of three parts (by weight) of gum shellac and one part india rubber. Dissolve in separate vessels in ether (free from alcohol), applying a gentle heat. When both are entirely dissolved mix them and put them in a tightly corked bottle.

TUNGSTEN-ALLOYED iron or steel has great density of grain; only traces of oxygen and nitrogen have been discovered in its analysis. This accounts for its ductility and tensile strength. The addition of tungsten to iron and steel is the best preventive known for decomposition. Water-mains, gas-pipes, and steel structures containing as low as $\frac{1}{2}$% tungstic acid will resist electrical, chemical, and atmospheric influences.

PICTURES may be transferred for stereopticon use in lecturing by the following process. Dissolve 1 bar of common soap in 1 gal. of hot water, then add $\frac{1}{2}$ pt. turpentine. Let stand over night, stir well and bottle. Apply the solution to the picture with a small brush, lay the picture on the film or plate, then apply a clean cloth or paper to the back of the picture and rub with the bowl of a teaspoon, when the picture is instantly transferred.

CAST-IRON TANKS may be repaired by a cement composed of five parts of sulphur, two parts of black-lead, and two parts of sifted cast-iron filings, the whole melted at a slow heat, to prevent the sulphur catching fire. Before applying the cement, warm the metal by laying a red-hot iron over it. The metal must be perfectly dry, in order not to generate steam. Then stop up the damaged parts with cement, applied in a soft state by gently heating it in an iron ladle.

CHROMITE is a massive black mineral that resembles magnetite, but can be distinguished from it by the reactions which it gives for chromium before the blowpipe. An unscientific but useful means of recognition is that chromite commonly is associated with serpentine. This mineral is the source of the various chromium compounds used in calico printing, electric batteries, the chrome colors and pigments, and in the manufacture of chrome steel. In its raw state it is made into chromite fire-bricks, and finds a ready market.

TO QUICKLY cut threads on a long bar a tool made thus will prove useful. Swing a tap, with the desired number of threads per inch to be cut, between the lathe centres, and gear the latter to cut the same number of threads as on the tap. Start the lathe and feed the tool against the tap until the threads are cut to full depth in the tool. The tool should be wide enough to cover four or five threads, and after they are cut the leading threads should be filed off, leaving the last one a full thread. Harden and temper the tool as any other. In using the tool it should be held squarely against the shaft to be threaded. A full thread can be cut in two or three cuts, thus saving about three fourths of the time it usually requires to do the same work with an ordinary threading tool.

BARITE is a heavy white or light colored mineral having the composition $BaSO_4$. It may be distinguished from other light colored minerals by its high specific gravity, insolubility, and its green flame. It is frequently found in beds and veins with ores of antimony, copper, and lead, also as veins and masses in limestones. Most of the American production comes from North Carolina, Virginia, and Missouri. The white variety is ground and used as an adulterant for white lead and for weighting paper; the colored varieties are often cut into paper weights, vases, and other articles of use and adornment.

TOPOGRAPHIC MAPS of the United States are issued at frequent intervals by the United States Geological Survey. From 25,000 to 30,000 square miles in different parts of the United States are mapped each year by the Federal topographers, under R. B. Marshall, chief geographer. This mapping is done in the field, and the sheet shows every physical characteristic of the area surveyed, as well as all works of man. The contour lines which show the configuration of the country—the hills, slopes, valleys, and peaks—are printed in brown; the rivers, swamps, lakes, and other water features in blue; and the county lines and other political subdivisions, railroads, wagon-roads, houses, and other evidences of civilization are printed in black.

A BELT can be made endless when both pulleys over which it must pass are on shafting which is supported on pillow blocks, in the following manner. As it is necessary to join the ends of the belt in place, a belt clamp is generally used. Place each end of the belt in the clamps with a square, and screw down the nuts to prevent the clamps from slipping. In drawing the ends together stretch both sides equally so as to make a straight joint, and draw the belt taut. When partly tight, turn the pulleys to get the belt on the pulleys taut also. If the belt is too long, cut off the ends and prepare them as before. The best clamps for cementing are made of two pieces of 4 or 5-in. scantling, with a bolt through each end. Cement the width of the clamps. Slip the clamps over the part cemented and draw them down by the bolts in the ends, and let remain a few minutes. Cement as much more, moving the clamps over the new cement, as before. It is best to have the clamps crowned in the middle so as to make equal pressure across the joint. Apply the glue or cement hot, with a brush. If the proper cement is used, no rivets will be necessary.

ALL THE ammonium nitrate explosives are quite deliquescent, absorbing moisture from the atmosphere very readily, and great care should be exercised in storing them or using them in damp places. They are not suitable for use in wet mines. If an original package of an ammonium nitrate explosive is opened in such a mine and the cartridges are exposed for only a few hours to the damp atmosphere they will deteriorate; many of the failures to completely detonate can be attributed to this cause. The ammonium nitrate explosives when stored under favorable conditions for only a few months show signs of deterioration, and nearly all explosives of this class after six months storage at the Pittsburg testing station have failed to detonate, or detonated incompletely when re-tested. For this reason ammonium nitrate explosives should be obtained in as fresh condition as possible and should be used as soon as possible after their receipt. Ammonium nitrate explosives, when in a fresh condition, have the advantage of producing on detonation but small quantities of poisonous and inflammable gases and are especially recommended for mines that are not unusually wet and also in mines and working places that are not well ventilated.

Special Correspondence

LONDON

Wallis Properties in West Africa.—More Businesslike Methods.—Mining and Milling Methods at South Crofty, Cornwall.—New Methods of Work.

About a year ago I sent several paragraphs describing the activities of the Wallis Syndicate in West Africa. This syndicate owns the mineral rights of a large tract of country in West Africa near the source of the Pra river, and about 60 miles east of Obuasi and Kumassi. An extensive outcrop of auriferous conglomerate, containing large boulders, was discovered two years or more ago, and it was traced for many miles. The syndicate's shares were quoted at fabulous figures on the Stock Exchange, and financial assistance for development purposes was sought from various mining houses. The Consolidated Mines Selection Co., Ltd., after sending F. F. Sharpless to examine the property, bought a block of shares and guaranteed the issue of a further block. Work was subsequently commenced for the purpose of proving the deposits by means of seven shafts. The last report received was despatched on May 31, and it shows that the seven shafts have been sunk to depths of from 67 to 108 ft., and that 640 ft. of driving has been done. This work revealed a condition that was not suspected from surface indications: the lode was found to be much broken and faulted: so much so that no reliable estimate could be made of the amount or regularity of the gold content. As far as sampling could be done the lode was found to vary in width from 2½ to 11 ft., with assays from 3 to 30 dwt. Investigation has shown that the faulting is not great and the chances are that the disturbance is only local. Consequently it has been decided to sink two of the shafts farther in the hope of finding the vein intact. The work is now being done in a miner-like way, and the information given out is quite different from the secret and mysterious talk of untold riches that characterized the early operations.

Last week I referred to the reorganization of the board and management at the Carn Brea & Tincroft mine in Cornwall and expressed a belief that the new blood on the staff in the person of Edward S. King and H. Swan Edgar would work wonders. I have always written pessimistically about the condition into which Cornish mining has sunk, of the hand-to-mouth policy of the Cornish boards and engineers, and of the old-fashioned and out-of-date methods of finance and mining, but I have always noted the exceptions. This week the excellent progress at South Crofty must be recorded. This mine was worked for many years by Camborne people, until the financial partnership involved broke down and no more money could be provided by the owners. Five years ago the Allen-Meyerstein group in London took up the property and provided adequate working capital. Sixty modern stamps were built, modern concentrating tables were introduced, and magnetic separators provided for the separation of the tin and wolfram. The greatest credit must be given to Francis Allen, a London lawyer, who has been chairman of the company from the start. He has shown great enthusiasm and optimism, and though naturally not an expert in mining and metallurgy, he has the knack of finding out men who are, and of employing them on liberal terms. Other London people in a similar position to Mr. Allen have not displayed the same discretion, and have squandered money wholesale. The result is that South Crofty is now in a good position. During the last few months the high price of tin and wolfram has helped greatly, and at the same time the grade of the ore has improved. For the first six months of this year, 31,205 tons of ore yielded 341 tons of tin concentrate that sold for £38,882, 71 tons of wolfram concentrate that sold for £7513, and 410 tons of refined arsenic worth £3910. The value per long ton was therefore 32s. 2d. and the cost per ton, including expenditure on new plant and development and every other expense, was 21s. The board now makes it a practice to pay 1s. per £1 share every quarter and to put the rest to reserve. I wish to point out that the directors are pursuing a policy which is quite usual elsewhere, but is never adopted in Cornwall, even by the few sucessful and well managed mines. In Cornwall it seems to be the desire to rub along somehow, so low-grade ore is mined in times of high prices of metal, and high-grade ore (when obtainable) when the price falls, instead of mining good quality ore when the price is high and so providing the capital which is so much needed. The South Crofty directors are greatly to be commended in taking advantage of higher grade ore at times like the present, and so putting themselves in a position where they can afford to feel independent of the ups and downs of the metal market. Another excellent feature of the South Crofty management is that development is well ahead of the mill and that the engineer, Josiah Paull, can estimate his ore reserve as a three years supply. Such a thing as an estimate of the ore reserve is elsewhere practically unknown in Cornwall.

MEXICO

Santa Gertrudis Reduction Plant Operates.—Greene-Cananea Shows Increase.—Tigre Cyanide Plant Opened.—Taxco Railroad.—Many Labor Strikes.

The Santa Gertrudis company (Camp Bird) has marketed the first bullion from its new reduction plant in the Pachuca district, and soon the plant will be running at full capacity. Test runs have been in progress for a month. There are sixty 1550-lb. stamps, and it is expected that each stamp will average over 10 tons daily. The tube-mills number ten. The company has straightened and retimbered the old San Guillermo shaft of the Santa Gertrudis properties, equipping with a 300-hp. electric hoist, and all ore for the new mill is hoisted through this shaft, delivery being made by conveyor belt. With the new plant operating at capacity, Santa Gertrudis expects to earn about ₱250,000 monthly.

Greene-Cananea reports that the production cost of copper at Cananea now is slightly less than 9c. per pound. At the present price of copper, and the present production of Cananea, this cost means that Greene-Cananea is earning at the rate of 65c. per share. In June the company produced 3,462,000 lb. of copper, 102,606 oz. of silver, and 509 oz. of gold. The June production of the Moctezuma Copper Co. (Phelps-Dodge) was 2,071,060 lb. of copper. In the first six months of this year the Moctezuma produced 12,528,889 lb. of copper, as against 11,617,818 lb. in the corresponding period of 1910, and 11,914,690 in 1909.

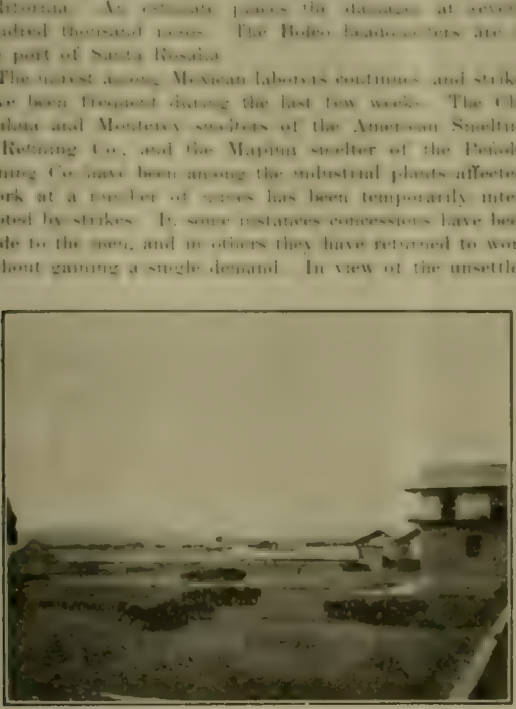
The transmission of power from the Copper Queen smelter at Douglas, Ariz., to the Tigre camp of the Lucky Tiger Gold Mining Co. in Sonora, a distance of 72 miles, has been commenced. The new 250-ton cyanide plant has been placed in commission, and the power is also operating the remodeled and enlarged crushing and concentrating plants. A big saving will result from the present power arrangement. Later, current will be furnished to other mining concerns in the Tigre camp.

The Chicago men who last year secured a concession to build a railroad connecting the Taxco district of Guerrero with the Balsas line of the National Railways have not abandoned the project, announcing that construction will be started shortly. F. E. Olendorf, a well-known mining man of the Taxco district, is representing them. The line will be 30 km. long, and will be of great benefit to the mining industry in that section of Guerrero. T. R. Marshall, general manager of the Taxco Mines of Mexico, Ltd., a British concern operating the old Rosario mines in the Taxco district, has left for London and Edinburgh, to complete arrangements for the erection of a large cyanide plant. The company has been carrying on extensive development work, and has had very satisfactory results.

In the State of Jalisco several companies that suspended operations last year are resuming. The Keystone Mining Co., of Shamokin, Pa., a reorganization of the Keystone Copper Smelter Co., organized by Philadelphia men several years ago to work copper-silver-gold [illegible] [illegible] [illegible] district, will [illegible] [illegible] [illegible] [illegible] [illegible] center. The new [illegible] will replace two old [illegible] now [illegible] the camp.

It is reported that the Boleo Copper Co., controlled by the Paris Rothschilds and one of the principal copper producers of Mexico, recently suffered heavy damages as a result of a hurricane that swept the east coast of Lower California. An estimate places the damage at several hundred thousand pesos. The Boleo headquarters are at the port of Santa Rosalia.

The unrest among Mexican laborers continues and strikes have been frequent during the last few weeks. The Chihuahua and Monterey smelters of the American Smelting & Refining Co., and the Mapimi smelter of the Peñoles Mining Co. have been among the industrial plants affected. Work at a number of mines has been temporarily interrupted by strikes. In some instances concessions have been made to the men, and in others they have returned to work without gaining a single demand. In view of the unsettled labor conditions, the Guggenheim interests have curtailed operations in several States, pending improvement. The earnings of the National Railways for the month of June show a decrease of ₱731,071, compared with June of last year. The earnings of the merger system for the fiscal year ended June 30, were ₱61,806,288, an increase of ₱323,141 compared with the preceding fiscal year. The big earnings of the first six months of the last fiscal year offset the big decreases of the last six months.



SANTA GERTRUDIS PATIO, PACHUCA.

According to New York reports, the sale of the Pearson oil interests to the Texas Oil Co., headed by John W. Gates, has been practically arranged. However, Lord Cowdray, head of the Pearson interests, who has been conferring with officials of the Texas company in New York, has issued a denial. It is rumored that the Maderos would oppose a transfer of the Pearson concessions as they stand, but there is no confirmation of this. The Magnolia Oil Co., of Texas, a new concern that combines the holdings of the Securities Oil Co. and the Gulf Refining Co. in that State, is reported to have entered into a contract with the Huasteca Petroleum Co., a Doheny concern, for the purchase of Mexican crude oil for refining in Texas.

GOLDFIELD, NEVADA

Development Work Active at Douglass.—Goldfield Con. M. Co.'s Post-Dividend Balance Largest in History.—High-Grade Ore Held in Reserve.

In Mineral county, 7 mi. west of Sodaville, Douglass is reviving in activity owing to discoveries made on the Tennessee group, purchased recently by G. C. Webb, a mining engineer and metallurgist from South Africa. At the upper end of the group a shaft had exposed ore that panned freely, but the new work farther down the hill, where a shaft has been started, has exposed 6 to 7 ft. of high-grade ore assaying from $75 to $2500 per ton with many assays from $[illegible] to $[illegible]. The ore is a light porphyritic substance, closely filled with seams of highly oxidized quartz, and, while little gold is visible, excellent pannings are obtained from samples taken across the vein and from the dump. At other points along the vein surface cuts have exposed rich ore. The veins are within dikes of blue andesite and andesitic breccia, cropping boldly, and the walls are as uniform as if built of masonry, indicating, throughout the district, but rare instances of fault displacement. The camp has a record of $600,000 production in the nineties, but was nearly depopulated and work almost entirely suspended by the rush of many inhabitants to the camps of Goldfield and Tonopah. It is reported that work will be resumed on the Douglass holdings. Mr. Webb has taken a lease on the Stewart 5-stamp mill at Sodaville. The Davenport, Oriole, Little Chief, and Wheeling Gold Range companies, the last named having copper instead of gold and being over the ridge to the south, are all developing. Excavations are completed and part of the equipment is on the ground for another 5-stamp mill to be in operation within 90 days, and the camp has an ample supply of good water. It was the only gold-producing camp at the time of the discovery of Goldfield and is apparently destined to become an important factor in the production of gold in this State.

In the final report of operations of the Consolidated Mines Co. in June the general superintendent, J. F. Thorn, shows that the month's total production was 28,540 tons, containing $923,472.87, or an average of $32.36 per ton, of which the whole was milled with an average extraction of $30.63 per ton, or 94.64%. The total net profit to the company was $646,830.48, or $22.67 per ton. Development work for the month amounted to 4376 ft. Operating costs were: Mining (development $1.04 and stoping $2.37) total, $3.41; transportation, $0.10; milling, $2.19; marketing, $1.15; general expense, $0.68; bullion tax, $0.38; construction, $0.15; total cost of operation, $8.06. Regarding conditions at the mines, the report says:

"Combination Mine.—The orebody just west of the 136-ft. stope was extended considerably and yielded a large tonnage of 2 to 3-oz. ore. We have also cut a very promising looking quartz mass nearly vertically under this orebody on the third level.

Mohawk Mine.—In this mine the 354-sill floor was considerably extended and produced 1068 tons of $19 ore.

Clermont.—The sill floor of the 413 intermediate, between the 600 and 750-ft. levels, was considerably extended, and produced 1413 tons of $60 ore. What is probably the downward extension of the 354-ft. orebody was cut from the 306 drift, about 500 ft. northwest of the Clermont shaft. Not enough work has been done, however, to prove the extent of this orebody.

Red Top.—The 403 sill was extended along the hanging wall and produced 250 tons of $40 ore. On the third level, 100 ft. north of the main cross-cut from the shaft, 260 tons of new ore worth $15 per ton was mined.

We are installing a 50-hp. electric hoist on the Jumbo shaft, which should be in operation within ten days. Recent sampling indicates a large tonnage of $20 to $30 ore remaining in this property."

The Jumbo workings will give the Consolidated seven producing shafts, the Combination, Mohawk, Clermont, Red Top, Grizzly Bear, Laguna, and Jumbo. Checks are being mailed for dividend No. 12, to reach all stockholders on July 31. This is the sixth consecutive quarterly dividend at the rate of 50c. per share, amounting to $1,779,574, and brings the dividend payments of the company to a total of $16,366,609. After the dividend is paid the company will have a cash balance of approximately $1,985,000, the largest post-dividend balance in its history. After the last dividend the balance was something over $1,640,000, and net earnings for the calendar quarter ended June 30 were about $2,120,000, or over $340,000 above dividend requirements. It is said upon good authority that there is a large tonnage of high-grade ore blocked in the mines and which is being held for the purpose of sweetening the leaner ore as it may be required.

BLACK HILLS, SOUTH DAKOTA

Tinton Properties Active.—Mogul Employees Plan Original Research.—New Mark in Gold Production.—Record Silver Shipment to Mint.

A small crew of men is employed at the Tinton property, in western Lawrence county, developing the orebody. The company hopes to start its tin mill at an early date. At the Ruby property, near Tinton, the shaft is being sunk to quartzite, which diamond-drilling has disclosed at a depth of 325 ft. D. N. Huff, of Spearfish, is manager. At the sale of the Hidden Fortune property, held by Kirk G. Phillips, receiver, the ground and personal property of the company, including a 40-stamp cyanide mill, was sold to the creditors for $46,000.

Employees of the Mogul Mining Co. have formed the Mogul Research Society, and will undertake cyanide tests along lines pertinent to Black Hills practice. A well equipped laboratory has been fitted up. Monthly meetings will be held. At the first meeting, held in July, the most important topic was a discussion of Mr. Chase's article on the Liberty Bell mill, which appeared in the *Mining and Scientific Press* of June 24. From the program tentatively adopted for the coming winter's work, some interesting papers and discussion will be had.

According to the figures given out by the United States assay office at Deadwood, the office during the quarter ended June 30 purchased gold bullion of a gross value of $1,889,000. This was the largest business ever transacted by the office, and indicates the general prosperity of the district. This production was made almost entirely by the Homestake, Lundberg, Dorr & Wilson, Golden Reward, Mogul, and Wasp No. 2. With a number of mills starting, it is expected that the production will be larger for the next quarter and that without a doubt the calendar year will show the largest output ever made by the district. An order to increase the 'assaying and stamping' charge which is imposed on bullion deposited at this office was postponed, to take effect from August 1 to January 1. The increase of this charge would have driven a large amount of the bullion produced in the district to be shipped direct to the Denver Mint. This would be cheaper for the producers, but their returns would be delayed. R. J. Gamble, Senator from South Dakota, was instrumental in securing the postponement of the date of effect of the charges, and hopes to have the order cancelled after the matter is thoroughly discussed. On July 1 the assay office sent off to the Denver Mint the largest shipment of bullion ever made from the district. It comprised over half a ton of bullion and had a value of close to half a million dollars.

The Columbia mine, at Keystone, has just completed a test run in the Tykoon 10-stamp mill. The plant is antiquated and not equipped for a close saving of the ore, but the results are satisfactory. The run was made at the instance of probable purchasers. An option on the Golden Slipper mine, at Hill City, has been obtained by prospective purchasers, who are making an examination. The last milling tests made showed that while a large portion of the ore contained in free gold, a considerable saving could be made by installation of concentration and cyanide equipment. The Forest City, adjoining the Golden Slipper, has been bonded by Salt Lake people, at a purchase price of $30,000, of which one-tenth is payable immediately. The shaft is 63 ft. deep, showing from 1 to 4 ft. of high-grade free-milling ore; it is described as one of the best-looking prospects in the district. The annual report of the Mogul Mining Co. for its fiscal year ended March 31 shows that the bullion returns from 114,873 tons of ore milled were $376,121.29. Milling was accomplished for $1.1026, according to John V. N. Dorr, consulting engineer, and a recovery of 76.5% of the gold and 35% of the silver made. However, the silver is of minor importance. With the tube-mill, which is now in operation, a higher saving is expected. W. L. McLaughlin, general manager, says: "We have opened up at the different mines probably more ore than we ever had, and at the present time the grade is better than it has been for a long time and promises to continue so. At the Farm the most promising development which we have is on the new Sunnysides, where we have a large body of ore which is of better grade than anything we have had for several years." The mine was shut down at the beginning of the fiscal year, owing to labor troubles, and did not get to running smoothly until July or August, and even then some trouble was experienced. Edward Manion, mine superintendent, in his report says, concerning the labor situation: "The class of employees which we have at the present time is better than it was when we were employing union labor, and everything is working smoothly and satisfactorily." The outlook for the present fiscal year is excellent.

PRINCE WILLIAM SOUND, ALASKA

New Copper Mines to Ship Soon.—Gold and Copper in Interior.—Two-Hundred-Stamp Mill at McKinley Lake.

Two new copper mines are to be opened this year on Prince William sound, already with its present two shippers the heaviest mineral producing district, by tonnage, in Alaska. It is believed by some that within a short time Prince William sound will ship regularly 60,000 tons of ore per year. Two steel freight steamships have been placed in service for Prince William sound. To the production of the mines mentioned will be added the output of the Bonanza mine, which is shipped from Cordova, the port of the sound. The Bonanza, at Kennicott, the Beatson Bonanza, on Latouche island, and the Ellamar M. Co. at Ellamar, the three large shippers, judging from the ore now blocked out, and the estimated amount for future working, probably will remain regular shippers for a long time.

The Bonanza ore is of extraordinarily high grade, previous shipments having assayed from 60 to 74% copper. A large amount of machinery is being installed, and by fall it is believed the Bonanza will have trebled its present output. Ellamar and Beatson ores are low grade, as are Sound ores generally. The two mines expected to become regular shippers during the summer are the Dickey, on Landlock bay, and the Fidalgo Bay Copper Co. The Latouche Ltd. M. Co., by J. A. Murphy, is developing a property on the east side of Latouche island, and Francis A. Hancock, in charge of the Reynolds mine, is developing property three miles north of the Beatson mine. F. Hodges, of W. A. Hodges & Sons, Salt Lake, and W. T. and F. H. Oster, have opened an assay office at Cordova. New rich gold and copper discoveries have been made by men sent into the interior from Cordova by the United States M. S. & R. Co., the London Exploration Co., and the Pierson Syndicate. Individual prospectors have bonded their properties without trouble.

The Mother Lode property, which joins the Bonanza on the other side of the mountain, is now being examined, and it is expected that this property will be worked, beginning this fall. Samples of ore have run as high as 70% and there seems to be an immense quantity above 50%. The Copper River & Northwestern railway has completed a survey from Mile Post 192 to the Mother Lode property, and four miles out on this new survey still another spur has been run to cross the range and enter the White River country, where good quartz outcrops are reported. In the event of these two districts, the White River country and the Mother Lode district, warranting action, the railroad will be built. Henry Bratnober, who represents the London Exploration Co., officially announces that if development on the McKinley Lake property justifies it, a 200-stamp mill will be erected. Kenneth Kerr, agent, the Alaska Steamship Co., recently returned to Seattle, taking with him 4000 lb. of samples of copper ore from the famous Bonanza mine. One of the samples weighs 1500 lb. and is a splendid specimen. These samples will be sent to the New York Land & Irrigation Exposition, to be held at Madison Square Garden in November, and will form part of a general exhibit which Alaska will make at this exposition. Agents are now going through Alaska gathering mining and general exhibits.

NEW YORK

British Interests in Porcupine.—Cobalt Mergers.—New Issue by the Camp Bird.—Ratification of Leroy Sale.—Increase in Calumet & Hecla Surplus.

Aside from the appalling loss of life, the recent fire in the Porcupine district is now looked upon as a real benefit. The destruction of the muskeg, the consequent exposure of the quartz outcrops, the doing away with the breeding places of the black flies, are real helps for the pioneers. Owners of undeveloped claims not within the fire zone are unanimous in regretting that the flames did not reach them, and so save them a large part of the future work of trenching and clearing. At the moment steamship lines are profiting very largely by the Porcupine situation. English capital has had a much more extended education in low-grade gold mining than has the investor on this side. As a result, many Americans are going abroad with investments at present, and it is said that many British engineers are going back and forth, and that the interest in London is increasing. The Kerr Lake interests have taken over some Porcupine properties and have organized the American Goldfields, Ltd. Edward Steindler, president of the Kerr Lake, is also president of the new company. An early merger of the Beaver Con. and the Temiskaming M. Co. of Cobalt is expected. Both properties now pay small dividends.

Cable advices state that the £500,000 of debentures, issued by the Camp Bird, Ltd., at the time of the purchase of the Santa Gertrudis, are to be retired by a new stock issue of 750,000 shares, £1 par, of 7% preferred stock. Of this 100,000 shares is to be retained in the treasury and 650,000 shares sold, the proceeds to be used in taking up the debentures outstanding. The Tomboy Mining Co. has just issued a statement regarding the negotiations now on foot with the Revenue Virginius for the acquisition of the latter property. The sale of the Leroy mine to the Consolidated Mining & Smelting Co. of Canada, made by the liquidators of the former company for the sum of $250,000, has been unanimously ratified by the shareholders. Ohio Copper seems left almost wholly friendless. A large block of the bonds sold recently at auction at $20, and 10,000 shares of stock were disposed of at auction one day this week for $1.75 per share. The stock was said to have been bought in by a Guggenheim representative, and there is some talk of a possible Guggenheim absorption of the property.

Notwithstanding that the past year has not been generally any too prosperous for copper producers, the Calumet & Hecla annual report shows an increased disbursement in dividends and an increase in the surplus carried forward. During the calendar year of 1910 dividends paid were $2,900,000, as compared with $2,700,000 paid during the previous twelve months. Profit and loss surplus was $8,576,856, as compared with $7,667,298 for 1909. The total dividend record of the Calumet & Hecla now totals $113,450,000.

In view of growing importance of the porphyries, the items of tonnage and copper costs in the Lake region are of greater interest than those of dollars and cents. On the Conglomerate lode, the scene of the most important operations, the company stoped 1,950,040 tons at a mine cost of $2.13 per ton. The tonnage handled is practically the same as that for the two years preceding. The copper produced was 58,739,509 lb., being in round numbers 8,000,000 lb. less than the year previous and 12,000,000 lb. less than 1908. Copper costs were 8.55c. per pound, against 7.77 in 1909, and 8.38 in 1908. On the Osceola lode there was produced 13,150,427 lb. of copper at a cost of 10.53c. per pound. On the Conglomerate the ore ran 30.12 lb. of copper per ton, the ore-value steadily declining. On the Osceola lode the ore showed 15.82 lb. per ton. The constant problem of the Calumet & Hecla is to win an undiminished return from rock which as constantly decreases in copper content. The very devices used and the progress made in handling large tonnages at a minimum of cost have in a great measure made available the low-grade milling coppers that for the time being are in command of the copper situation.

The British Columbia smelter is operating despite the coal miners' strike at Crows Nest Pass. Coke from the Pittsburg ovens is being shipped in to the Granby and the Consolidated Mining & Smelting Co, as well as the British Columbia. The latter is handling about 2000 tons per day, of which about one third is taken from the New Dominion.

TORONTO, CANADA

Substantial Reconstruction for Flame Swept Porcupine.—Losses Overestimated.—Value of Cobalt Ore Shipments Greater Than Last Year.—Large Dividends Paid.

The work of reconstruction after the Porcupine fire is being rapidly pushed, and the primitive structures swept away by the flames are being replaced largely by buildings of a more substantial character. As usual in such cases the first reports as to the loss of life and property by the catastrophe were greatly exaggerated. The actual number of known deaths to date is 67, and the extent of territory ravaged by the fire, according to official information, is about 10 miles square, comprising about two-thirds of the townships of Whitney and Tisdale, in which most of the larger mining properties are situated. The fire which destroyed Cochrane, 30 miles distant from Porcupine, had no connection with the greater disaster. The destruction of stakes on claims swept by the fire is likely to result in much trouble and confusion, as it will be difficult to identify many of the properties. On the other hand, a great stimulus will be given to prospecting by the removal of the vegetation and overburden and the exposure of the rock.

The West Dome will at once proceed with the erection of fireproof buildings of steel and concrete. John B. Cleveland, of Prescott, Arizona, has been appointed manager in place of Robert A. Weiss, who lost his life in the fire. The temporary working plant of the Vipond, which was destroyed, will be replaced as soon as possible by the permanent equipment for which estimates had been made before the fire. The Preston East Dome saved the greater part of its milling machinery, and its principal loss will be a month's delay in operations. The United Porcupine will rebuild at once and continue operations on a larger scale. At the Dome the fire which destroyed the buildings and plant, exposed bodies of quartz and schist which are regarded as adding materially to the available orebody. A new vein which has been found on low ground is regarded as equal to any on the property. The loss by the Dome Extension was small and work is being resumed. A new shaft is going down on an orebody about 100 ft. wide some 600 ft. from the main shaft. The Rea was not reached by the fire. The main shaft is down below the 118-ft. level and good ore is being taken out. At the Foley-O'Brien work was not interfered with. The big vein has widened to 55 ft. at the 160-ft. level. Ten more stamps have been ordered for the Hollinger, bringing the number up to 40. Four tube-mills will be installed, which it is calculated will increase the crushing capacity to 350 or 400 tons per day. The vein recently picked up in the northeast section of the main claim is being proved by a raise.

The half-yearly report of Arthur A. Cole, mining engineer for the Temiskaming & Northern Ontario Railway Commission, gives the shipments of ore from Cobalt for the six months ended in June as 11,978 tons, as compared with 14,868 tons for the corresponding six months of last year. The report states that the falling off in shipments must not be taken to indicate a decrease in production. The fact that higher-grade ore on the average has been shipped and that considerable bullion has been sent out, will bring the total valuation above that of last year.

A geological survey report just issued on the Big Horn coal basin, in Alberta, estimates that there are 6,600,000,000 long tons of coal, in an area of about 187 square miles, that are workable. The Big Horn basin is about 85 miles northwest of Banff, 140 miles southwest of Edmonton, and 70 miles south of the surveyed routes of the Grand Trunk Pacific and Canadian Northern Railway routes.

General Mining News

ALASKA

Of the $10,273,000 in gold received by the assay office at Seattle during the year ended June 20, $8,922,000 was sent from Alaska. This amount was in addition to shipments of gold sent by several of the largest corporations direct to San Francisco for smelting. The latter shipments in some instances were the total output of the mills.

Installation of power plants by two independent power companies, states S. R. Guggenheim, has afforded facilities for dredging earlier and later, lengthening the season a month. Last year the Guggenheim dredges were closed November 5, against October 1 in 1909. This year the first dredge commenced operation May 4, against May 22 the previous season.

The Copper River & Northwestern railroad is planning to equip its engines to burn oil, and a contract for a supply from California fields has been arranged. It also is probable that many of the mining properties will use oil for fuel. The Alaska Northern railroad, operating from Seward to interior points, has imported a gasoline motor car for passenger service and will use imported coal for only heavy freight.

The new placer discovery on Nansen creek is reported to be the best in Yukon for several years. The average yield is reported 2 cents per pan.

Juneau District

(Special Correspondence.)—In the contest between the Ebners and Alaska-Juneau companies over disputed ground, the court decided that neither had made a valid discovery and that therefore the ground was still in the public domain. The Alaska-Juneau, having made an appropriation of the water, was allowed to retain it, thereby winning a substantial victory.

Juneau, July 10.

Prince of Wales Island

(Special Correspondence.)—The sale of the Mt. Andrew mine on Prince of Wales island to the U. S. S. R. & M. Co. failed to go through, owing to differences as to price, though the examination showed the presence of a good body of valuable ore.

Cordova, July 11.

Valdez District

(Special Correspondence.)—James M. Hall has taken a bond on the Cogeshall group of claims at the head of Mineral creek. The purchase price is stated to have been $50,000, with the first payment of $2500 due January 1, 1912. A party of Chicago men, including George B. Harris, Samuel Scotten, J. G. Snydaker, G. W. Buckley, and Fred H. Weaver, have been visiting B. F. Millard and examining the properties in which they are interested with him.

Valdez, July 12.

ARIZONA

The value of the output of the mines of Arizona for 1910 was less than that for 1909 by $717,462.63, according to official reports recently filed with the territorial auditor.

Yavapai County

(Special Correspondence.)—Messrs. Griffin and Filmore, California oil experts, have gone to San Francisco for drills for claims in the Verde valley. Prescott residents have located claims all around the proposed drilling spots.

The A. T. & S. F. R. R. Co. is securing the rights of way for a standard-gauge road to supplant the United Verde narrow-gauge railroad. It will reach the United Verde property nearly 1000 ft. lower than the town of Jerome. The line later may be extended to Humboldt, by way of the Cherry Creek mining district. Much placer gold is being saved from small creeks started by recent heavy rains.

Prescott, July 22.

CALIFORNIA

The oil production of California during June, according to Bakersfield reports, was 6,526,661 bbl., with a daily average of 217,555 bbl. The San Joaquin valley yield was 4,949,805 bbl., against 5,083,116, although the daily average was slightly higher than for May. The southern fields produced 986,331 bbl. and the coast fields 590,525 barrels.

The Standard Oil Co. has bought in fee all of Sec. 3 and 4, 27-21, in the Lost Hills, according to report.

Butte County

(Special Correspondence.)—William C. Ralston, Assistant United States Treasurer, has been at Forbestown to let contracts on the Burlington mine for tunnel work in 100-ft. drifts. The mine is being blocked out by tunnel, drifts, and shaft to figure on an increase in the capacity of mill already planned. The company may erect a 100-ton stamp-mill this season if developments continue as encouraging as present assays show. Recent assays give the 3-ft. vein an average of $10 which will be the means of deciding for the company the erection of a 300-ton stamp-mill in the spring.

Forbestown, July 16.

Inyo County

The 12-stamp Merrall mill at the Tuba Canyon mine will be running in 30 days. The mill, capacity 50 tons per day, and cyanide plant, capacity 50 tons, are set up, and water is being piped. The vein averages 4 ft. wide. The ore averages $15 on the plates, according to report, and $6 cyanide. C. H. Brown is superintendent.

W. C. Price, an oil man of Los Angeles, is opening up the Wild Rose mine, formerly a Harrisburg property.

Mariposa County

(Special Correspondence.)—Another ore-shoot has been opened in the Bondurant mine in Coulterville on the 150 and 200-ft. levels. A dike which cut the vein at this working was driven through, and Mr. Gerkin, superintendent for the present company, was greeted with a glitter of specimen ore. The best ore is being sacked and the balance is put through the 10-stamp mill. Two 10-ton Pierce amalgamators have been installed after the plates. Two Union concentrators were placed early in the month. About 20 men are employed in the mine.

During the past week about 25 millwrights and carpenters have arrived, to work on the new mill at the Oro Rico mine. The frame timbers are on the ground, and the lighter parts of the mill have been hauled from Pleasant Valley. A pipe-line is being laid from Black creek.

Friction among the stockholders which was the cause of the temporary suspension of work at the Crown Lead Mines last winter, has been settled and work resumed on lines of development. Mr. Ireland is the new manager, with William Webb as foreman in charge of a force of ten men.

The machinery formerly in use at the Champion mine is being hauled to the Bluejay mine, and the outlook is very encouraging, according to statements made by Al. Sturzinger, superintendent in charge.

Coulterville, July 22.

Nevada County

(Special Correspondence.)—The 32-ft. rise from the 600-ft. adit at the Snowden Hill gravel mine has exposed the channel. Samples of ore show gold in commercial quantities. A drift is being driven at the rate of 12 ft. per week, shortage of water-power greatly handicapping the work. The property is controlled by Boston people. J. B. Martin is president. The Blue Lead, Bonanza, Eureka Lake, and Waukeesha gravel properties at Relief Hill, near North Bloomfield, have been merged under one management. A company is being formed to work the properties. W. F. Englebright and J. Oscar Jones, manager of the Blue Lead, are moving spirits in the new concern. The holdings comprise 1400 acres of land, with approximately two miles of gravel channels. The properties are located on the Big Blue Lead, the most famous gravel deposits in this section of California. It is reported that the deal involved $100,000. The ditches are being repaired and it is announced that development will be pushed. The gravel deposit of the Central Consolidated, on Banner hill, is reported to be showing good values. The mill is operating steadily on low-grade quartz. A 3-ft. vein has been found at the Sleeping Beauty, Moore's Flat district. The ore carries ribbon quartz and arsenical sulphide, but no assays have been made as yet. The property is controlled by San Francisco capitalists. Walter Muller is president. An improvement in the gravel channel is reported from the Posey Canyon, at Grass Valley. Gravel mining is attracting renewed attention throughout the county, several properties that have lain idle for years recently receiving attention.

Nevada City, July 22.

Plumas County

(Special Correspondence.)—Work at the Bushman placer mine is being rushed to open an old channel. H. C. Adams is in charge. The 10-stamp mill at Twain, operated by the same management, is milling some good ore taken from the Adams mine at that place. The quartz vein is about 3 ft. and is being blocked out with a view to enlarging the mill.

Twain, July 27.

Shasta County

(Special Correspondence.)—The Noble Electric Steel Co. is completing arrangements for the resumption of electric iron smelting at Heroult. Local and San Francisco foundrymen pronounce the Heroult product of exceedingly high quality. The Delta Consolidated Gold Mining Co. has completed a 550-ft. spur track from the shaft to the railroad and is about to commence shipping ore to the Mammoth smelter. The company has dispensed with ore-bunkers, loading the ore in cars direct from the shaft, and plans to ship custom ore from other small mines in the Dog Creek district. A 4-ft. vein assaying $15 per ton has been found in the Scottish Chief at a depth of 160 ft. The property is situated near Redding. Mat Vandiline is manager.

GENERAL VIEW OF BALAKLALA SMELTER.

The Balaklala Copper Co. has recently suspended all work at Coram. Fully 2500 people are more or less affected by the closing of the big plant. In their mad haste to prove their power over the smelter operators, the local farmers have killed a profitable market for their products.

Redding, July 24.

COLORADO

Denver County

Mining men here have suggested the use of the large testing plant under construction at the Colorado School of Mines, Golden, for experimental work by the U. S. Bureau of Mines. A $40,000 appropriation is available for investigations to reduce costs of metal production and make profit from deposits not now worked. Other suggested sites are Silverton, Denver, Pueblo, or some other mining school.

The Denver Chamber of Commerce is planning to organize a $2,000,000 company for the development of mining prospects in Colorado. The control of the company, which will be known as The Grubstake & Development Co., will remain with the Chamber of Commerce, which is to control 1,010,000 of the 2,000,000 shares. The other shares will be sold to the public at not less than par, as preferred. Ten per cent of the earnings will go to the common stock, with 90% available for dividends on the preferred. Recently a $10,000 fund for providing grubstakes was raised by popular subscription.

The North American company's Golden smelter is handling more ore than at any previous time under the present ownership. The ore is principally from Clear Creek, Gilpin, and Boulder counties. The policy of acquiring more property to insure a continuous supply of ore is followed.

Douglas County

The source of the gold in Cherry creek is believed to have been discovered, says a report from Newlins gulch, in an 8-ft. wide dike a short distance above the old diggings. No placer gold has been found above the dike.

San Juan County

Silverton is to have a reduction plant that will put profit into the zinc of the mixed sulphide ores. Arrangements for the construction of the mill have been completed. The Huff electrostatic separator will be used.

Lake County

Development at depth in the Sugar Loaf section of the Leadville district indicated the coming transformation of the region into a great copper camp. Placer mining for gold was the first activity in Leadville. Then followed the discovery of immense silver-bearing lead-carbonate deposits in blanket formations. Later some of the mines became producers of high-grade gold ore. Of recent years the production of zinc sulphide ores has been an important industry, and only last year large deposits of zinc carbonates that had previously escaped detection were found and have added largely to the yearly output of the district. Within the last few years also exploration has disclosed huge ore-shoots in fissure veins that extend through the overlying limestone and quartzite down into the granite. Two years ago, J. D. Irving, then with the U. S. Geological Survey, was quoted as saying: "The Sugar Loaf section will be a second Butte when you have attained the depth. The formation is exactly the same, and if you should put a Butte man into one of the Sugar Loaf properties without letting him know where he was, he would say he was in Butte." Ore running from 3 to 8% in copper is now taken from Sugar Loaf mines, and mining men here believe that in a few years Leadville will be a great copper camp, the first in Colorado.

Ouray County

A vein 4 ft. in width averaging $24 per ton in gold is reported in the tunnel driven by the Angel M. Co., which owns 3000 ft. on the Bimetallist vein and 4500 ft. on the Lloyd vein. The ore was found at the intersection of the two veins. This property, as well as the Virginius, the Camp Bird, and the Atlas, is in the Sneffels district of Ouray county. In the Red Mountain district on the Indiana group, owned by T. B. Crawford of Denver, a 5-ft. orebody 250 ft. in length has been opened, and a large production is assured. The Wanakah company, which has been making a regular production from the Bright Diamond and adjoining claims near Ouray, has bought the Orient group on Cascade mountain, and is planning systematic development.

Teller County

A regular quarterly dividend of 3c. per share has been declared on all outstanding stock of the Vindicator Con. Gold M. Co. of Independence.

IDAHO

Idaho County

Washing gold on the Hydraulic Placer Co.'s ground on Salmon river, 15 mi. below the junction with Snake river, will begin in August. There is an unlimited supply of water, and the giants will be under 65 lb. pressure.

Owyhee County

Ore assaying $59 per ton, asserts the *Owyhee Nugget*, was discovered on Cuddy mountain by Thomas Towell when he was digging an irrigating ditch. The vein has been traced over 1000 ft., and three men are at work.

Shoshone County

The lower adit on the Copper King M. Co. property at Mullan, now at 808 ft., will be completed. An ore-bearing stratum has been developed, but it is not considered a true fissure vein. An assessment of 1c. per share has been levied.

Directors of the Jack Waite mine in the Coeur d'Alene have decided to drive a new 2000-ft. tunnel to gain a depth of 1000 ft. Work has been started on a new compressor. Fritz Marchante, of Spokane, is president of the company, succeeding Patrick Burke.

The management of the Hypotheek mine near Wallace, reports that the building for the 20-ton mill will be completed the middle of August.

Active work will be started on the Coeur d'Alene-Mastodon mine as soon as supplies and equipment can be assembled there, according to J. H. Lever, manager of the property. A crew of five men and a pack-train of supplies have been sent forward.

MICHIGAN

Marquette County

The local committee on the Menominee range has selected Tuesday, Wednesday, and Thursday, August 22, 23, and 24, as the dates for holding the sixteenth annual meeting of the Lake Superior Mining Institute, and the council has voted in favor of this. Arrangements are now under way for the entertainment of members, and circulars will be issued containing the itinerary of the trip, together with a list of papers to be read, also any excursion features which may be decided upon.

MISSOURI

Jasper County

The American Zinc, Lead & Smelting Co. is reported to have leased 110 acres southeast of the Eastern Lead & Zinc Co.'s development work.

The Sitting Bull mine at Thoms station is reported to have turned out recently 142,800 lb. of zincblende in 9 hr., or two 70,000-lb. cars of concentrate.

A rich discovery of zinc and lead ore on the Alamo property is reported by T. C. Clary and Edward Sparrow, who hold a lease on a portion of it.

Phelps County

J. A. Holmes, recently here en route to Alaska, before the Missouri School of Mines advocated a combination of "persons or capital or holdings or mineral properties for operative purposes" in the coal business. The elimination of the middleman through the organization of a single syndicate he believes would result in a saving to the consumer. Coal production profits have been narrow for some years, says the Colorado State Board of Immigration, and mining men of that commonwealth also favor the plan.

MONTANA

Lincoln County

Work on the Snowshoe mine, one of the oldest in the Coeur d'Alene district, has been resumed. E. H. Wilson, manager of the mine and consulting engineer to the Pacific Coast Smelting, Refining & Mining Co., states that the 300-ton mill there is treating from 200 to 250 tons of ore daily, and that 1000 tons of concentrate is on hand. The latter averages between 50 and 60% lead, 14 and 20% iron, 25 oz. silver, and between $12 and $15 in gold per ton. The company has bonded the Silver Tip group of four claims making the southern extension of the Snowshoe property.

Silverbow County

The new compressed-air hoisting plant at the Mountain View shaft of the Anaconda property is reported to have proved very satisfactory. It was placed in commission last month. The Diamond shaft, and later the High Ore shaft, soon will be similarly equipped. The Anaconda is using electricity for power to a constantly growing degree. It is hoped that the present cost of producing copper will be decreased ½c. per pound.

NEVADA

Esmeralda County

(Special Correspondence.)—Conditions in the Rawhide district are improving, with 16 blocks of ground receiving attention. In several cases owning companies are conducting work, but mostly operations are in the hands of small lessees. Lack of capital continues to be keenly felt, also absence of adequate mining facilities.

Rawhide, July 23.

(Special Correspondence.)—At the 800-ft. level of the main Florence Goldfield shaft a station is being cut while the shaft is being sunk to the 1000-ft. level and new territory is being opened on the 500 and 650-ft. levels. Some ore of excellent quality is being taken from the new workings on the 500-ft. level as well as from the stopes on the 360-ft. level at the north of the Florence claim, in the Reilly vein. Laterals will be driven without delay on the 800-ft. level to open several of the orebodies from which a large production has been made on other levels nearer the surface. A change has been made in ore treatment. The Florence mill has installed an Akins classifier and a Dorr pulp thickener, eliminating the Deister concentrators and Frue vanners, and effecting the extraction almost entirely by amalgamation and cyanidation. The mill soon will be treating 170 tons per day with an increased recovery.

The Jumbo Extension Co. is making good progress in development at a depth of 1030 ft. on its Polverde claim, adjoining the Clermont and Jumbo claims of the Consolidated on the east. The interrupted work on the Annex lease on this claim is being resumed on a more liberal scale than in the past.

Goldfield, July 23.

Eureka County

Samples of copper ore from a 40-ft. shaft in the Copper Basin district, 12 mi. from Mineral hill, averaged 18.15% from top to bottom, with 8 oz. silver. A prospect hole 600 ft. north of the shaft, 4 ft. deep, showed 18.6% copper with 10 oz. silver.

Lincoln County

The final papers in the acquisition by the Nevada-Utah company of the Ohio-Kentucky and Con. Pioche properties have been transferred. E. R. Woolley, president of the Nevada-Utah, states that development on a huge scale will be furthered at once.

Nye County

The Tonopah M. Co. during June treated 14,113 dry tons at its mill, with an average value of $23.13 per ton of ore. The Tonopah Belmont company treated 6640 dry tons at its mill and shipped 2117 dry tons direct to the smelters. The ore averaged $31.30 per ton, about $1 higher than in May. The Tonopah M. Co.'s ore averages were $21.76 in May and $18.03 in April.

A discovery of $100 to $150 gold ore is reported on the Crescent claim. The vein is 18 in. wide and specimen ore shows some free gold.

M. J. Fink is planning extensive development of the barytes deposit on Lone mountain, 14 mi. northwest of Tonopah. Shipments will be considered as soon as a satisfactory rate to tidewater can be arranged.

The new shaft of the Halifax mine has been started. Driving will be started at the 1500-ft. point to strike the big Belmont vein. M. L. McDonald is resident agent.

Piute County

Rich discoveries are reported at Ten Mile camp, 12 mi. southwest of Marysvale. The district is virgin country. The lowest gold assay on the DeWitt claim is reported to be $44 per ton. The Cameron Pride, Sidney Black, manager, is operating near there. Other owners are James Long, C. Voigt, James Neilson, and the DeWitt interests.

WASHOE COUNTY

W. S. Foskey and associates have acquired from the Sierra Wood & Lumber Co. a 10-year lease of the old Hobart estate, and will prospect for the [illegible] bonanza.

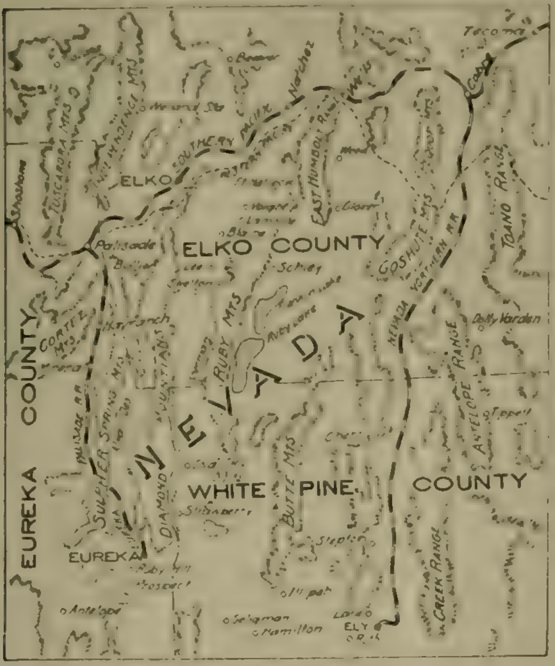
WHITE PINE COUNTY

(Special Correspondence.)—The Ohama company, at Sacramento pass, is doing considerable development, and has a milling plant of 30-ton capacity about ready to run.

The Centennial Developing Company is sinking a winze from its adit level which will be continued until the water level is reached, where it is expected that the secondary enrichment will be found.

The Greek-American Mining Co. last week purchased the Simon Davis group of claims in the Aurum district, 30 miles from Ely, upon which it has commenced development work. The mines show about 1000 tons of shipping ore in sight, which will be hauled to the railroad at Warm Springs and shipped to Salt Lake City smelters for treatment.

The Ely Revenue company, which has been idle for several years, has been reorganized, and resumed work this week. The company has about 200,000 tons of gold ore in sight, which will average better than $10 per ton. The company expects to erect a gold mill at the property next year. The Ely Consolidated company has reached its 600-ft. level and is now cross-cutting for orebodies on that level. This property joins the Nevada Consolidated on the south, and is showing much good ore on the 400 and 500-ft. levels.



MAP OF EASTERN NEVADA.

For some weeks past the Boston Ely has been developing orebodies on its 1245-ft. level, and is now placing an additional 80-hp. engine and another air-compressor. The ore development on this level is considered sufficient by the management to justify the company in installing a pumping plant and working the level. The company has been operating steadily for the past five years, and deserves much credit for its persistent efforts.

Ely, July 20.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The last bullion clean-up at the Deadwood mines amounted to 5200 oz. troy, gold and silver, with 25 sacks concentrate. The mill is handling 20% more ore than had been figured on. Last week 420 tons of ore was treated with 25 sacks concentrate.

The first 10-day clean-up for July at the Ernestine M. Co. showed 621 [illegible] oz. troy, gold and silver bullion, and 4½ tons concentrate. Seven hundred tons of ore was treated last week. It is reported important improvements will follow a visit by the vice-president next week.

The Oaks Company has finished a bridge across the arroya north of the adit portal and all grading has been completed.

A number of new contracts have been let in the lower levels of the Socorro mines. One thousand tons of ore per week is handled.

The Enterprise M. Co. plant soon will be ready for a test run.

Rain increased the water at the hydro-electric plant, and the Treasure M. & R. Co. mill is in full operation. More than 50 tons per day is hauled to the mill and treated.

Mogollon, July 22.

OREGON

BAKER COUNTY

The old Evening Star mine, Gimlet creek, has been abandoned temporarily owing to its cutting a watercourse.

W. I. Spencer, T. B. Neuhausen, of Portland, and Mohr have bought the Bi-Metallic mine near Greenhorn. A 500-ft. cross-cut is planned to tap the Bi-Metallic vein 300 ft. below the present deepest opening. Both gold and silver ore is produced there.

PENNSYLVANIA

ALLEGHENY COUNTY

The Pittsburg Coal Co.'s production for the six months ended June 30 was about 6,000,000 tons, a decrease of 550,000 tons, or 7½%, on account of low prices. July shipments compare better with those of July last year than the May and June shipments for the year's change.

UTAH

SALT LAKE COUNTY

The Inspiration Copper Co. soon will construct a 5000-ton mill. C. H. Repath will be in charge.

The Thompson-Quincy Con. Co. of Park City has acquired all outstanding stock of the old West Quincy company and is sole owner of 180 acres of patented land between the Daly West and the Daly-Judge mines. The drainage dispute has been settled.

UTAH COUNTY

Work on the Bonneville M. Co.'s adit near Provo will be resumed in the near future with three shifts of men operating Burley compressed-air drills. It is one of Jesse Knight's projects.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The Butte & Boston, Chico, Jim Blaine Fraction, and Emma Fraction, contiguous claims in one group, have been leased and bonded to W. M. Crummer, formerly superintendent of the San Poil and Black Tail mines, in Republic camp, and A. W. Beckett of Republic.

Work has been resumed in the Trade Dollar mine, with the intention of raising from the No. 1 level to the adit which cuts the vein south of the shaft.

Republic, July 22.

J. L. Harper, general manager for the Republic M. Corporation, reports an important discovery on the 200-ft. level of the Surprise mine. The ore varies from $30 to $45 per ton. This, known as the 'Danny shoot', is believed to be a continuation of the Bonanza zone. The Republic M. Corporation shipped 1700 tons of ore in June.

The First Thought mine, in the Orient district, is reported sold to an English syndicate for $8,000,000, the deal involving a 10% first payment. The company is to be reorganized, some of the original owners retaining an interest in the company, and a large cyaniding plant is to be built. The deal has been pending a year. The mine has about 1,000,000 tons of ore running $8.50 per ton on the dump, and it has been estimated there is from 15,000,000 to 20,000,000 tons of gold-bearing ore in the property.

The Republic Mines Corporation shipped during the month of June 1700 tons of ore, all from the 200-ft. level of the Surprise mine. At the Quilp mine the principal work is confined to the vicinity of the winze below the 500-ft. level. Conditions in the Lone Pine mine are satisfactory; rapid progress is being made in driving on the 400-ft. level; ore is being blocked out in large quantities, ready for stoping.

Stevens County

(Special Correspondence.)—The Germania mine, on a suit for $1200 due for merchandise, has been placed in the hands of a receiver in bankruptcy, George H. Baker.

The Alice E. mine, owned by the Alice E. & Morning Star Mining Co., in Orient district, will resume operation with a force of 30 men under the management of George Robertson.

It is reported that the Standard Oil people will build a smelter, in opposition to the American Smelting & Refining Co. In connection therewith comes the statement that A. D. Goodell, formerly manager of the Northport smelter, at Northport, is taking up new contracts as fast as the old ones expire.

Orient, July 25.

CHILE

O'Higgins

Work on the new concentrator on the Braden property in O'Higgins province is being pushed and the first unit will be operated this month. The second unit will be operated in September, and the third in November, according to report. It is expected that No. 4 Fortuna adit will strike the main orebody in the near future. No. 4 is 750 ft. below No. 3½ adit, which is only half way through the orebody, where important developments are taking place. Reports state that 1,000,000 tons of 'probable' ore has been developed. The April estimate was 12,000,000 tons assaying 2.7% copper. Of the 5,000,000 tons added later, 1,000,000 tons was actual and 4,000,000 probable. An advance of 23 metres was made in Fortuna adit No. 3½, the ore averaging 2.85%. The first left cross-cut in Teniente adit No. 1 was advanced 23 metres in ore averaging 4.14%. Pope Yeatman is consulting engineer to the company.

CANADA

Alberta

The First Thought gold mine has been sold by Patrick Burns to an English syndicate for $8,000,000, according to report. It was among the first of the mines opened last year at Orient camp.

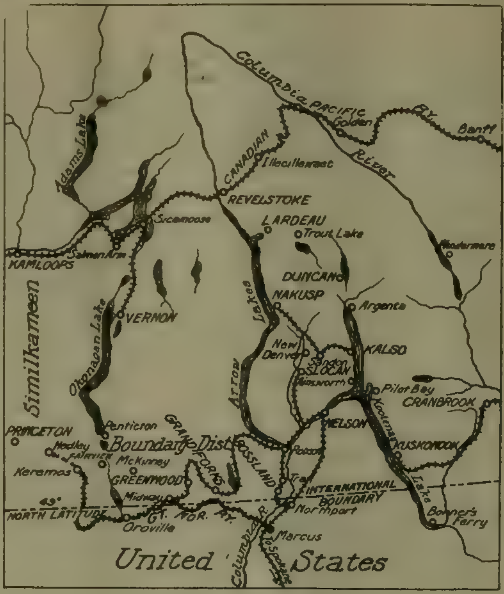
FIRST THOUGHT MINE.

British Columbia

It is said that the Con. M. & S. Co. is soon to work the Le Roi mine at Rossland. This company bought the property from the Northport Smelting & Refining Co. for the reported price of $250,000 a short time ago.

At Athin, B. C., the hydraulicking season has opened and J. M. Ruffner, of the North Columbia G. M. Co., has 15 giants at work.

Big Tunnel mine at Greenwood, B. C., probably the first mining enterprise in America subsidized by a municipality, reports a lateral depth of 2400 ft. and a vertical depth of 1200 ft., with rich ore showings. When the tunnel reaches a lateral depth of 5000 ft. a raise will be made for air. The tunnel company will then receive the first installment of the $50,000 which was voted by the citizens of Greenwood. The striking of the lead at 1800 ft. from the mouth of the tunnel proves there is plenty of high-grade ore at depth. The ore is the same as that found on the Providence mine, which shipped to the extent of $500,000 a few years ago.



BRITISH COLUMBIA.

MEXICO

Chihuahua

The Reform M. Co., organized to take over the Hinds Con. Mines Co., will not resume work until after the October elections, according to report. F. A. Matthew, it is said, will be in charge.

Durango

A bond and lease on the El Fuerte property, 39 acres; bond and lease on the Aguaje, 19 acres; full rights on the Little Anna, 17 acres; full rights on the Catalina, 10 acres; full rights on the Santa Isabel, 10 acres; and a Durango State mill concession for a cyanide mill have been secured by the newly organized Western Durango Mining & Development Co. John Allingham and J. H. Hedges will be in charge.

Guanajuato

The shaft of the Mineral Development Co. at Guanajuato is down over 2000 ft. and a cross-cut will be started for the Valenciana vein from the 1968-ft. level as soon as the 14-in. spiral ventilating pipe is installed. H. Vincent Wallace is manager.

Jalisco

The Consolidated Mining Co., owning the Casados mine in the Hostotipaquillo district, has during the past four months shipped ore of a value of $100,000, all of which was taken out in the course of development work, no stoping having been done. The shipments have been made to the smelters at Torreon and San Luis Potosi. A big tonnage of milling ore has also been developed in the Casados, and the present reserves are sufficient to keep a 250-ton mill busy for several years. Work is in progress on a 150-ton reduction plant, and it is expected to start milling before the end of this year. W. R. Ramsdell, one of the principal American operators of this section of Mexico, is at the head of the Consolidated Mining Company.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Stephen Birch is at Cordova, Alaska.

G. M. Clark, of Placerville, has gone East.

F. F. Sharpless has been at Seward, Alaska.

D. J. Muir, Jr., has gone to Matanuska, Alaska.

James S. Wyatt has gone to the Altar district, Sonora.

J. B. Tyrrell has left Toronto for a short visit to England.

W. S. Noyes has gone to Colorado to be away four or five weeks.

Louis A. Wright left San Francisco on July 18, for a trip to Asia.

Rensselaer H. Toll is at Manhattan, Nevada, on professional work.

H. S. Chapman is in San Francisco on his way to Arizona on examination work.

William M. Brewer has gone to Alaska as manager for the Matanuska Gold M. Ltd.

P. G. Spilsbury is general manager for the Aguacate Gold M. Co. at San Mateo, Costa Rica.

J. S. Lockyer, director of the Solar Physics Observatory at London, was in Washington recently.

C. F. Dietz and D. V. Keedy, of Boston, have gone to Joplin in the interest of Boston people.

Frank H. Probert is at Ray, Arizona, and will proceed to Cananea before returning to Los Angeles.

H. Vincent Wallace is manager for the Mineral Development Co., Mina Nueva Luz, Guanajuato.

C. H. Repath has been put in charge of the offices of the Inspiration Copper Co., at Douglas, Arizona.

W. H. Weed was at Duluth recently, and has gone to Porcupine, returning to Butte toward the end of the month.

Arthur J. Hoskin is consulting engineer for the O'Reilly Gold Mines Co., on North Star mountain, Summit county, Colorado.

Gustave M. Gouyard has returned to New York from a two months' trip on professional business to Sonora and Chihuahua.

H. F. Lefevre has returned to New York from South America and sailed for Central America July 27, to be gone three months.

Boyd Dudley, Jr., instructor in metallurgy and ore-dressing at the Missouri School of Mines, has been granted leave of absence.

R. B. Lamb, of Toronto, has left for an extended trip to Cobalt, Porcupine, and Swastika, to inspect properties and make examinations.

G. W. Schneider, of Denver, has been elected professor of mining at the Colorado School of Mines, Golden, with Carl A. Allen as assistant.

L. C. Barlow, manager for the Metals Buying & Refining Co., at El Paso, Texas, is examining properties for Toledo, Ohio, people in the Porcupine district, Ontario.

The Mines Management Company has been retained to make an examination of the Carissa mine near Lander, Wyoming. H. P. Henderson has charge of the work.

Donald F. MacDonald, geologist for the Isthmian Canal Commission, has returned to his headquarters at Culebra, Canal Zone, from a profesional trip through Costa Rica.

J. D. Hubbard has resigned from the metallurgical department of the Oriental Consolidated Mines Co., to become superintendent of the Chosen Mining Co. in Yeng Byen province, Korea.

H. W. Edmondson has completed an examination of the Mejia mine in Planchas de Plata district, in Sonora, and is now reporting on the Volcancillo group near Autlan, Jalisco. He expects to return to Los Angeles next week.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

EVIDENCE—REPORT OF MINE SUPERINTENDENT

The statute of Illinois requires a mine superintendent to make a record of any accident occurring in the mine and to make a report of the same to the State Mine Inspector. Under this statute such a report and the record made by the mine superintendent to the Mine Inspector are admissible in evidence in the trial of a case for an injury to a miner to establish the facts required to be so reported and recorded; and the fact that such a report contained a statement that a piece of rock fell from the roof of the mine and struck a miner, and that the miner had a wife and child, would not operate to render such report and record inadmissible as evidence.

Aetitus *v.* Spring Valley Coal Co., (Illinois) 92 Northeastern, 579.

ESTATES IN MINERAL LANDS

A citizen may acquire any one of three possible estates in mineral lands upon the public domain. He may content himself with locating a claim in compliance with the statutes and rules and regulations, in which case he acquires a possessory title only, both the equitable and legal title remaining in the Government. In the second place, after making such location, he may comply with the further requirements of the law, and pay the required purchase price, thus acquiring the equitable title; the legal title still remains in the Government. Finally he may proceed one step farther and obtain a patent for the land, thereby devesting the Government of all interest both legal and equitable.

United States *v.* Rizzinelli. 182 Federal, 675. Aug. 1910.

COMBINATION TO PROCURE TITLE TO COAL LANDS

The fact that two persons engaged in an unlawful combination to procure title on behalf of a corporation to an area of coal lands in excess of the amount prescribed by law, and that lands in excess of the amount allowed by law were actually patented to them, would not make such patent valid, the unlawful combination making the proceeding illegal from the beginning. And a corporation formed to take over such patent lands is not a bona fide purchaser for value without notice to the extent that it precludes the Government from proceeding to cancel the patent, as the rule is that the person holding the voidable patent to lands can not protect himself against the process of the Government by forming a corporation in which he is the dominant factor and conveying to it the premises which he has acquired in violation of law.

United States *v.* Allen, 180 Federal, 855.

INSPECTION OF MINE—LIABILITY OF MINE-OWNER

The statute of Illinois requires a mine-owner to employ a legally qualified mine examiner to inspect the mine before miners are permitted to enter for work, and to see that all dangerous places are properly marked, as required by the statute. This statute is mandatory and not merely discretionary, involving only the exercise of good faith on the part of the mine-owner; and a mine-owner cannot excuse himself from liability for a failure to properly examine the mine and mark the dangerous places, even where the mine examiner and mine manager examined the place where the injury occurred, and in good faith believed it was not dangerous. And where the rock and other débris which fell and struck a miner, fell by reason of the condition of the roof of the mine before he commenced work, and whether the place should have been marked as dangerous, are questions of fact to be determined by a jury under the evidence.

Aetitus *v.* Spring Valley Coal Co., (Illinois) 92 Northeastern, 579.

Commercial Paragraphs

THE MINES MANAGEMENT CO., New York, announces that Gordon S. Duncan, with offices at 28-29 St. Swithins Lane, will act as its agent in London.

Joseph F. Spellman, representing the CHROME STEEL WORKS, Chrome, New Jersey, announces the removal of his office to 414 First National Bank building, Denver, Colorado.

The SULLIVAN MACHINERY CO. announces that in future its business in France will be in charge of Hart O. Berg, at 30 Rue des Champs Elysees, Paris. All Sullivan machinery will be carried in stock as heretofore.

The MULCONROY CO., Philadelphia, has purchased the business, machinery, and patents of the Metallic Flexible Tubing Co. of Philadelphia, and will continue to manufacture the well known brands of the latter concern.

THOMAS N. MILLER has bought the business of Lawrence N. Wagner, chemist and assayer, 24 Broad street, Nevada City, California, and will operate a custom mill in connection with the assay office and chemical laboratory.

The WOOD DRILL WORKS, Paterson, New Jersey, has adopted the use of vanadium tungsten iron in making the cylinder, chest, and the air-head of Wood rock-drills. The makers claim that the wearing qualities of the new alloy are much superior to cast iron and that it allows a freer movement of the piston.

THE DEISTER CONCENTRATOR CO., of Fort Wayne, Indiana, reports the following recent sales of its tables: Gorman, Clancy & Grindley Co., Calgary, Alberta, Canada, tables No. 3 and 4; Nova Scotia Silver Cobalt M. Co., Cobalt, Ontario, Canada, No. 2 tables; Mt. Champion Mining Co., through Stearns-Roger Mfg. Co., Denver, No. 2 and 3 tables.

ALONZO F. BARDWELL, who has been manager of the assay office of Bettles, Mathez & Co., Salt Lake City, for the past three years, has purchased the interests of Mathez & Co., and in future the firm name will be Bettles & Bardwell. Mr. Bardwell will continue to devote his entire time to the business, having brought with him the experience of 23 years in the work at Aspen, Colorado.

The BRODERICK & BASCOM ROPE CO., of St. Louis, represented by The Hampson-Fielding Engineering Co., of Denver, has been awarded the contract for the Mount Champion Mining Co.'s aerial tramway, having a total length of 6250 ft., with a fall of 950 ft. The carriers are the G. & S. patent, with phosphor bronze bushings, and the improved hanger arms. The buckets are also G. & S. patent automatic self-dumping, self-righting, and self-locking, performing all these functions without the assistance of an attendant. The loading terminals are peculiar to this design. The load is evenly distributed in the bucket, as it enters the bucket from two sides instead of one, and the bucket is not stopped in transit, the loading being accomplished while the bucket is in operation at its normal speed.

EDITORIAL

THIS is the first number to be issued from our new home at 420 Market street, San Francisco.

IT IS reported that the Postoffice Department is planning to establish an ocean mail service between the principal ports on the Atlantic and Pacific, by way of Panama and Colon.

THE UNITED STATES PATENT OFFICE has issued the astonishing total of one million patents, the millionth being for a new rubber tire. It would be interesting to learn how many have been issued for substitutes for rubber.

A FRENCH INVENTOR has patented a device to prevent an airship from turning over while descending. But it would seem that when the spot at which the airship strikes is of ordinary hardness, it would be almost immaterial which side up the aviator was at the moment.

CHARGES at the Government assay offices are to be doubled on January 1 next. Established when transportation was less abundant, these offices were of great service, but for many years past have been conducted at a loss. The office at Seattle assays much of the gold that comes from Alaska, and is likely to persist, but the increased charges are apt soon to remove from Deadwood, Carson, Salt Lake, Helena, and Boise these reminders of pioneer days.

A BILLION DOLLARS is a huge sum, yet the Bureau of Statistics of the Department of Commerce and Labor predicts that the exports of domestic manufactures of the United States for 1911 may exceed that amount. The increase in exports of manufactures for the year ended July 30 was 18½ per cent over the preceding year, nearly 100 per cent greater than in 1901, and 384 per cent greater than in 1891. Foodstuffs and crude materials show an equally remarkable growth. The imports of merchandise for the year show a decrease of 2 per cent in value, and even greater decrease in quantity, the excess of exports over imports being nearly half a billion dollars. But the amount of new securities issued yearly in the United States is so great that large amounts of foreign capital are necessary to keep up with our growing indebtedness.

The Cunningham Claims Decision

Few recent decisions of the Commissioner of the Land Office have attracted more attention than that which settled the so-called Cunningham claims. Interest in the matter is abundantly justified, not only by the merits of the particular case, but by the potentialities of the decision. There is a wide disposition to consider the opinion rendered as 'political,' flowing from a regard to the state of the public mind rather than a sound following of law and precedent. There is this much of justification for this point of view; the interpretation of the coal-land law laid down in this case is not one that has been commonly held in the coal-land States, and the new interpretation is, doubtless, largely the result of a new attitude of the public mind toward the public lands. This does not necessarily impugn the good faith or good judgment of those concerned. Whatever may be the opinion of anyone reading the documents in the case as to the propriety of selling large blocks of public coal lands to private individuals, there seems to us no room for difference as to the belief that the claimants were acting in strict accord with what they and their attorneys regarded as the law. Furthermore, anyone familiar with the operation of the coal-land laws in the West, will at once concede that thousands of acres of lands have passed into private ownership with much less right, and where the law was much less scrupulously observed. The Cunningham claimants proceeded under the law as they knew it, as it had been commonly interpreted, and in accord with the customs under which coal land had in the past been commonly entered and patented. The situation presents many analogies to that in which the oil-men in California found themselves when faced by the Yard decision. It should be clear that under such conditions a strong moral claim to protection may originate, even if the legal basis be inadequate. The Commissioner has placed upon the law what is substantially a new interpretation, though even for it some precedent was found. To the layman the interpretation seems essentially sound. In brief the statute requires the opening or improving of a 'mine' as precedent to patent, and no mine had been opened. In the very nature of things no mine could be opened until the patent had been granted, and on the basis of secure ownership, tipples, railways, terminals, and docks, all essential to the working of a mine, could be safely built. It must be obvious to anyone that in a wilderness, far from any local industry, no sane person will conduct a producing mine on public land prior to securing title to the property. It must be equally clear that under this strict interpretation there will be few additional mines opened anywhere except on private lands. It is one thing to buy land from the Government before opening a mine, and quite another to first erect expensive equipment, and begin shipping coal, and then take steps to secure title. The effect of the decision is that of ruling that there is no law under which coal land may be legally entered. The Land Office, finding itself beset with difficulties, has passed to Congress the long neglected task of revising the coal-land laws to meet the needs of modern industry. There is a wide gulf between a law which contemplates giving to an individual 160 acres for his exclusive use, provided he has previously opened on it a 'mine'—presumably a country bank to supply his kitchen stove with fuel—and the needed law under which contiguous tracts of coal land may be made available in area sufficient to warrant the investment demanded for a modern colliery, to say nothing of the transportation that must often be provided. Ostrich-like, Congress has kept its head in the sand and refused to see that conditions have changed. The lonely pioneer is no longer the only one for whom provision must be made. The individual 160-acre claim and the maximum 320-acre association claim are jokes and have been for years. By persistent refusal to provide relief, Congress has opened the way to frauds of many kinds, and, essentially, the Department of Interior has at last found public sentiment strong enough to cause it to refuse longer to go through the farce of administering inadequate laws.

The objection naturally arises that any law must be assumed to be capable of a reasonable and workable interpretation; that in enacting the coal-land laws Congress must be assumed to have had in mind the providing of some means for disposing of the coal lands. This is entirely correct, but following the ruling of the Commission to the effect that the act of 1904 was as titled, an amendment to the old and not an independent statute, it seems equally clear that Congress did not have in mind the granting of such areas of coal land as are necessary under modern conditions. It could not well have done so, since in 1873 the conditions themselves had not arisen. The individual and the small colliery were then the rule, and the laws followed the general model of those under which farms were given to citizens. The limitation as to size, the prohibition of the use of 'rights' more than once, the very wording of the law, indicate that only the old conditions were in mind. Successive Commissioners and Secretaries, helped by judges and attorneys, made the best of a bad situation, and actually a coal industry grew up in the West. Eventually the coal-land laws were extended to Alaska; with how little knowledge and thought is revealed by the fact that they were at first wholly inapplicable because the land was unsurveyed. This was remedied by another act permitting claimants to have surveys made at their own expense, and when in 1908 matters had come to a standstill another patch was placed on the crazy-quilt of legislation. It was characteristic, however, that the act of 1908 was only made to apply to those who had already acquired rights. There was not then, and there never has been on the part of Congress any broad statesmanlike consideration of the really vital questions at issue. Congress failed in its duty to provide any adequate law to meet the situation, with the result that a premium was placed on fraud, all claimants were branded alike as dishonest conspirators, and Government officials were held up to public disdain as complacent tools, or wooden-headed zealots. We believe the Commissioner and the Secretary were wise to refuse longer to accept the responsibility of winking at misinterpretation of the law, and of bringing its duty squarely before Congress, though we regret keenly the injustice to honest claimants that has ensued.

Alaska is suffering from having her resources locked up while the game of politics is being played at Washington. We are not the most enthusiastic as to the great market awaiting Alaskan coal, but it requires only the briefest personal contact with the land and the people to convince one that Alaskan coalfields should be opened at once. The opening of a colliery or two will not, we fear, bring true all the rosy dreams that have been born of the long nights and sunshiny summer days of Alaska; but it will relieve a situation of real distress and of rank injustice. We may well have differences as to a general land policy, but there should be no difference of opinion as to the advisability of opening one or two mines at once. It would even be better, we believe, to patent a few rankly fraudulent claims, if necessary, and then take such time as may be necessary for formulation of a really equitable plan for dealing with the coal lands. As for the Cunningham claimants, they have our sympathy. They have been caught by what is essentially a change in the 'rules of the game', after the play had started. Fairness dictates that some relief be granted them, as was done in the case of the oil-men in California. We understand that at one time the claimants were offered patent to the amount of land allowed under the act of 1908. If possible, the offer should be renewed, or some other adequate measure of relief afforded them. We believe in social progress, and we further believe that the Conservation program is essentially sound. Some injustice and hardship to individuals is inevitable in all change, but we also believe that the American people wish to be just and generous, and under the conditions, the Cunningham claimants are entitled to recompense for their time and money. The Government ought not to keep both the claims and the claimants' money. The responsibility for the whole matter is, however, now where it belongs—before Congress.

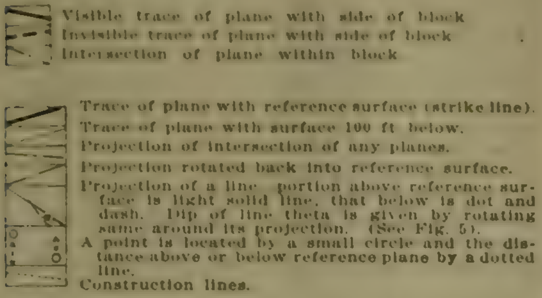
Graphic Solution of Fault Problems

By C. F. Tolman, Jr.

(Concluded from page 128.)

Where the fault movement is that of pure translation, and the fault plane is inclined. (Problems 8, 9, 10, 11, and 12.)

The scheme of lines chosen to represent planes, traces, lines, points, etc., used in this and preceding discussion, is shown by the legend below.



Visible trace of plane with side of block
Invisible trace of plane with side of block
Intersection of plane within block

Trace of plane with reference surface (strike line).
Trace of plane with surface 100 ft below.
Projection of intersection of any planes.
Projection rotated back into reference surface.
Projection of a line portion above reference surface is light solid line, that below is dot and dash. Dip of line theta is given by rotating same around its projection. (See Fig. 5).
A point is located by a small circle and the distance above or below reference plane by a dotted line.
Construction lines.

Problem 8. Fig. 8.—Given an inclined fault plane and the dip, strike, and total heave of both portions of two faulted strata (the total heave of one of the strata = *O*). To find the amount and direction of the total displacement. The analysis is the same as for problem 5.

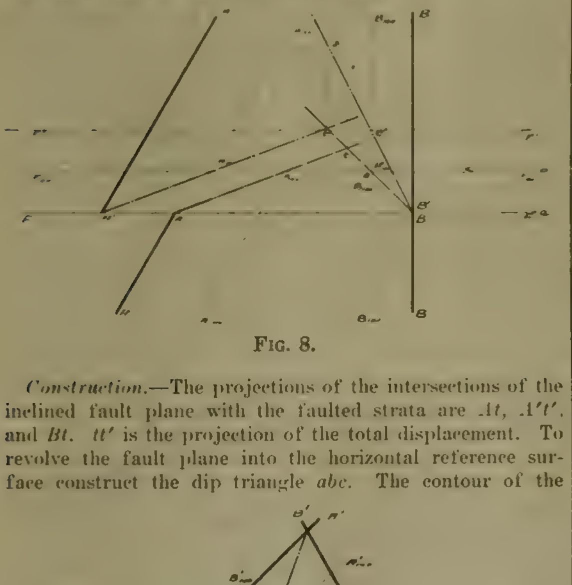


FIG. 8.

Construction.—The projections of the intersections of the inclined fault plane with the faulted strata are *At*, *A't'*, and *Bt*. *tt'* is the projection of the total displacement. To revolve the fault plane into the horizontal reference surface construct the dip triangle *abc*. The contour of the fault will move out until a distance from its surface trace = *ac*, assuming the position *F'F'*. *Be* moves out to *Be'*, and *tt'* to *xy*, which measures the magnitude of the total displacement.

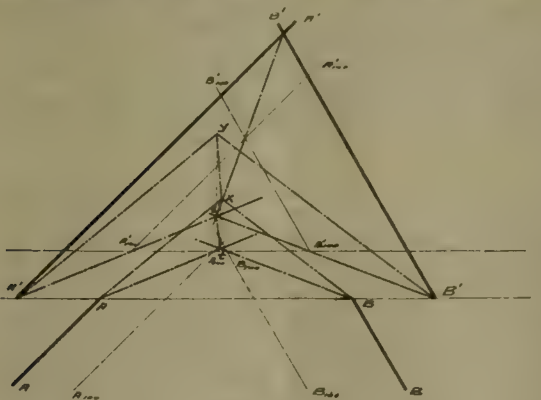

FIG. 9.

Problem 9. Fig. 9.—Given an inclined fault plane and the dip, strike, and total heave of both portions of two faulted strata. To find the amount and direction of the total displacement. The analysis is the same as for problem 5.

Construction.—Find the intersections of the projections of the fault plane traces of the strata on each side of the fault plane. These intersections are *t* and *t'*, and therefore *tt'* is the projection of the total displacement, the length of which may be found by rotating it into position *xy* which it assumes in the horizontal plane.

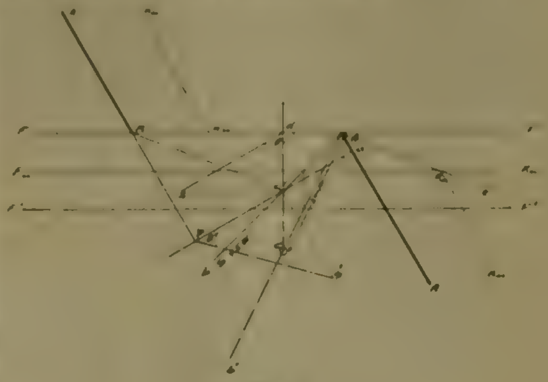

FIG. 10.

Problem 10. Fig. 10.—Given an inclined fault plane, and the dip and strike-line of one side of a faulted stratum, as well as the bearing and amount of the total displacement. To find the outcrop of the portion of the stratum on the other side of the fault plane.

Analysis.—After plotting the direction of total displacement, revolving its original (in the fault plane) into the horizontal position, the total displacement may be measured on this line from the intersection of the stratum and the fault plane, and the point thus found, when revolved back into the fault plane, will lie on the trace of the unknown portion of the stratum on the fault plane. Or, by determining the depth this point is below the surface, and projecting a line to the surface, in the direction of dip and at the angle of dip of the stratum, a point in the extended outcrop of the second portion of the stratum is determined.

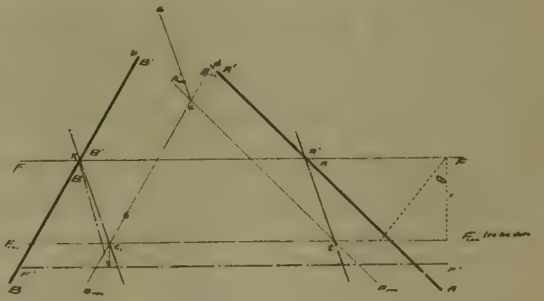

FIG. 11.

Construction.—*Ab* is drawn in the known direction of total displacement, and its original is revolved into the horizontal position *(Ab')* and the amount of the total displacement (200 ft.) measured on the same locates point *c*, which is revolved back to *c'*, and the trace *c'A'*, parallel to *At* is drawn, its intersection with *FF* locating *A'A'*. Or the distance *c'* lies below the surface *(c's and c's')* is used to construct the triangle *c's'p'*, drawn on *op*, which is perpendicular to *AA*, and Θ is the dip of *AA*. Point *p* lies on the produced strike of *A'A'*.

Problem 11. Fig. 11.—Given the surface trace of the fault plane, and the strike and dip of two faulted strata, neither of which are heaved. To find the dip of the fault plane.

Analysis.—Since neither stratum is heaved, (1) the traces (on the fault plane) of the two portions of either stratum coincide, and (2) they are parallel to the fault movement.

Construction.—Construct parallelogram *abcd*, *ac* is the one line common to both strata, and point *c* is 100 ft. below point *a*. Lay off xt_1 and parallel to *ac*. The contour of the fault plane passes through t_1 and its dip is Θ.

Problem 12. Fig. 12.—Given the strike of the fault plane, and the strike, dip, and total heave of three faulted strata. To find the dip of the fault plane.

Analysis.—The linear intersections of the strata on one side of the fault plane taken in pairs, will intersect in a point. A line drawn to the corresponding point on the other side of the fault plane will be parallel to and equal in length to the total displacement. The dip of the fault plane is determined by using the total displacement thus determined in combination with the dip, strike, and total heave of any faulted stratum.

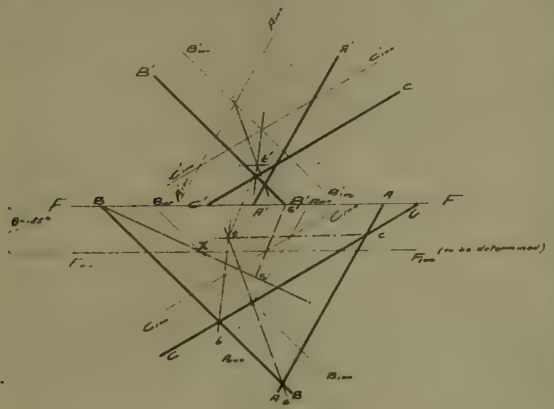

Fig. 12.

Construction.—Find any two of the three mutual intersections of the strata *AA, BB, CC (at, bt, ct)*. These intersect in a common point *(t)*, for each pair of lines lies in a common plane. *t′* is the corresponding point of *A′A′*, *B′B′*, *C′C′*. *tt′* is the projection of a line parallel and equal to the total displacement. Take *ss′* parallel and equal to *tt′*. *Bs* is the projection of the trace of *BB* on the fault plane, therefore its intersection with $B_{100}B_{100}$ at *x* locates $F_{100}F_{100}$, and the desired dip (Θ) is found by constructing the dip triangle.

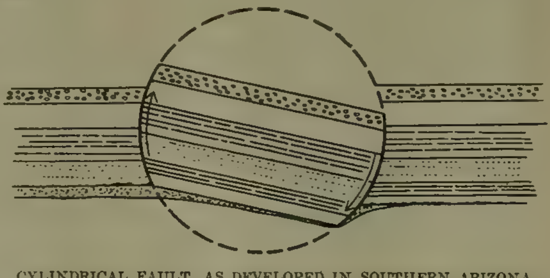
Discussion of the problems in which fault movement is that of pure translation. The above problems have been selected, not only to illustrate graphic methods, but to bring out certain features in faulting, which if borne in mind, may assist in approximate solutions, and emphasize those phenomena for which the investigator should be on the watch. It will be seen that there is no difference in attacking problems whether the fault plane is vertical or inclined, and that when the movement is of pure translation, the traces of each portion of a faulted stratum, in any plane, are parallel, and therefore a difference in strike on two sides of a fault indicates a pivotal component of fault movement.

Problems 5, 8, and 9 are examples of the solution of the important problem, which calls for the determination of total displacement when the fault plane is known, as well as the dip, strike, and total heave of two faulted bodies. The cases investigated where one of the strata is not heaved, are taken to emphasize that the offset at the surface is a function of the angle between the faulted displacement and the trace of the faulted stratum on the fault plane, and if the two are parallel, there will be no heave, regardless of the amount of fault movement. Problem 6 is an unimportant variation of problem 5, and problems 7 and 10 involve simple constructions often used in graphic solutions. Problems 11 and 12 involve the determination of the dip of the fault plane. In practice, when direct measurement of dip is not satisfactory, both dip and strike are generally determined by locating accurately three points on the outcrop of the fault plane, and determining their elevation and plotting these data according to methods of descriptive geometry. Problem 11 is theoretical, and is presented to show the possibility of the occurrence of an important fault movement, which nevertheless may not offset bodies with entirely different strikes (provided their intersections on the fault plane are parallel). Solution 12 may be occasionally of considerable importance.

Problems where a rotation about a pole is combined with translatory movement.

When combined rotary movement (about a pole perpendicular to the fault plane) with that of pure translation occurs, the angle between the fault plane traces of each portion of the faulted stratum measures the angular displacement regardless of the position of the pole. Almost every careful underground fault measurement will disclose such a variation of the traces from the parallel position, but generally so slight as to cause uncertainty as to whether this difference should be ascribed to rotation, or to minor irregularities of movement, or to faulty measurements. As already stated, cases have been reported of important pivotal motion, and as accurate, detailed observations increase, rotation will probably be found to be of more importance than suspected heretofore.

Solutions of problems in combined rotation and translation are greatly simplified by the following facts regarding faults. (1) Movements are so universally confined to definite planes that an ideal geometrical plane can generally be selected to represent the fault plane. (2) Fault fissures are universally closed. Any given earth movement will find complete relief (*a*) by a moderate amount of form distortion before the break takes place, (*b*) a movement between the two sides adjoining the fault fissure, and (*c*) a rock flowage by which that portion of the stress is relieved, that could not be satisfied by the fault displacement. This rock flowage caused by (*a*) and (*c*) must be considered in an investigation of the total deformation of an area, but in the practical investigation of the effect of an individual fault plane in displacing a lode, the consideration of rotary and translatory movements is made regardless of rock flowage. From this it follows that the pole about which rotation takes place is perpendicular to the fault plane. Otherwise one side of the fault plane must grind and the other gap. The initial position of the pole, which it would assume to give complete relief to the stresses, is probably not often perpendicular to the line of weakness that determines the fault plane, but molecular adjustment, which prevents the fissure from opening, etc., has the effect of raising the pole to the perpendicular position. The effect of simultaneous or subsequent warping of the fault plane, can generally be discarded in the simpler problems of individual displacements.



CYLINDRICAL FAULT, AS DEVELOPED IN SOUTHERN ARIZONA.

Certain 'strip faults',* by means of which an entire desert mountain range is given monoclinal dip, approach the form of a right cylinder. Such a form, if perfectly developed, could relieve both a rotation perpendicular to the end faces, and a movement parallel to the curved face, without an accompanying rock flowage. (See accompanying figure.) In the occurrences in mind, the cylindrical surface is represented by one or more great parallel faults, occurring as the main structural features of the region. The cross faults, on which the rotary movement should be expressed, are seldom developed, the rotation being satisfied by flowage, instead of fracture, and even when fracture occurs the cross-

---

*Tolman, C. F. *Jour. of Geol.*, Vol. 17, No. 2, p. 139.

faults are much more difficult of recognition than the parallel faults. Fault block systems are more common than single large strip faults, the blocks presenting a large variety of form, and here evidently only a portion of the movement block can find relief along the fault or planes, the rest going to adjust the form of the block to its new position.

Problems 12 and 13.—Given a fault plane, a pole, and angular displacement of *p* about the pole, and the dip and strike of two strata on one side of the fault plane. To find the outcrop and strike of the same on the other side of the fault plane, after both sides have been planed down to a common horizontal surface.

Analysis.—An auxiliary plane parallel to the fault plane should be constructed. The points where the pole pierces both planes can then be located, and these used as centres about which the fault plane and auxiliary plane traces of the given strata can be rotated. The points where these rotated traces of each stratum intersect the common level to which both sides are reduced, locate the strike line of the rotated portion of that stratum, the dip being determined from the rotated trace on the fault plane.

Case I.—The fault plane is perpendicular. Fig. 13.

Construction.—*FF* is the strike line of the perpendicular fault plane and *ff* of the auxiliary plane F_nF_n and f_nf_n being respectively the revolved position of their 100 ft. contours. Pass a perpendicular plane *RR* through the pole, and revolve it about its strike-line. R_nR_n is the revolved position of its 100-ft. contour, and the arrow shows the known revolved position of the pole, intersecting the fault plane and the auxiliary plane respectively at *p′ and* p_1'. The fault plane and the auxiliary plane, however, are revolved about their strike lines into the horizontal position, such a rotation bringing *p′* into the position *p″* and p_1' into the position p_1''. The traces *at* and *bt* are now rotated about *p″* through angle *p* into the positions *a′t′* and *b′t′*, and likewise in the auxiliary plane. a_1t_1 and b_1t_1 are rotated about p_1'' into the positions $a_1't_1'$ *and* $b_1't_1'$. Let erosion bring down the rotated block to the level represented by lines *FF* and *ff*. The intersection therefore of *a′t′* on *FF* and $a_1't_1'$ on *ff* locates the new strike-line *A′A′*, and *B′B′* passes through the intersection of *b′t′* with *FF* and $b_1't_1'$ with *ff*. Their dips are determined from their traces *A′t′* and *B′t′*.

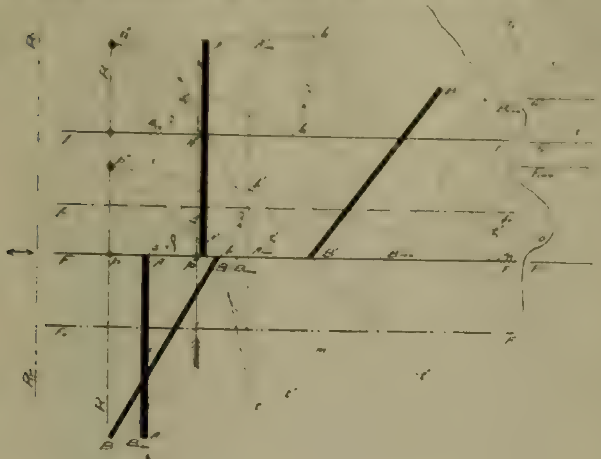


FIG. 13.

Case II.—The fault plane is inclined. Fig. 14.

Construction.—Inasmuch as the fault plane is now inclined, the pole shown in the revolved position of the auxiliary plane *RR*, has the inclined position $p'p_1'$, instead of a horizontal position as in the preceding case. It will be easily seen that when the fault plane and auxiliary plane are revolved on their strike-lines into the horizontal positions, the centres of rotation in these planes will be respectively *p″ and* p_1''. The rotation of the revolved traces *at* and *bt* about these centres and the determination of the strike and dip of the rotated portion of each is carried on as described for case I.

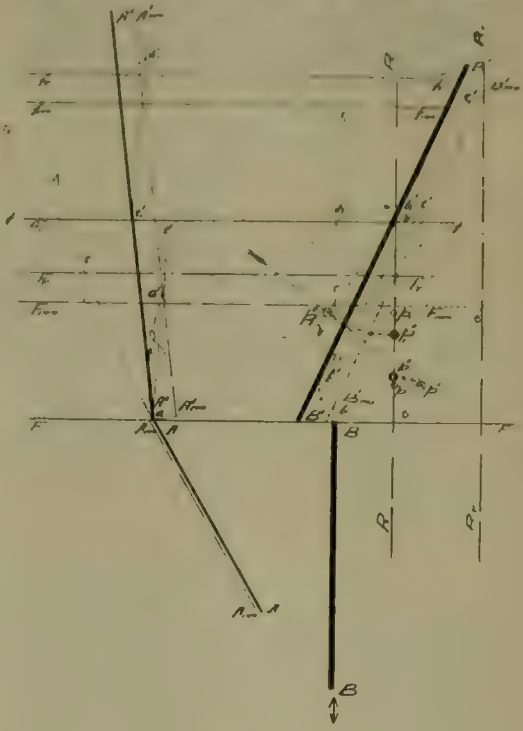

FIG. 14.

Discussion.—These two simple problems emphasize the following facts of practical bearing, which may assist in the detection of the existence of rotary movement, and explain some of the phenomena of faulting that otherwise would be difficult to understand. Assuming that fault movement is by angular displacement: (1) With a vertical fault plane, strata striking at right angles to the same suffer change in dip and not in strike. Others develop changes in both dip and strike after rotation. (2) Only those lines parallel to the pole will remain parallel to their original position after rotation. A strike line can be parallel to the pole only when the fault plane is vertical. Therefore when a stratum suffers a change in dip without a noticeable change in strike, the fault plane should be approximately vertical. (3) Very considerable heaves may be developed by a relatively small rotation, if the trace of the stratum is thereby caused to approach a horizontal position. For instance, in Fig. 13 if the stratum *BB* intersected the fault plane in the trace *bm* instead of *bt*, the faulted portion would have had outcrop *no* instead of *BB′*. Are not some of the thrusts described by geologists better explained by moderate rotations than by great translatory displacements?

Problem 14.—Given an inclined fault plane and two faulted strata, dislocated by a combined rotary and translatory movement. To find the equivalent pole about which it has taken place. Fig. 15.

Analysis.—The angular rotation *p* is the angle between the fault plane traces of the two portions of any faulted stratum. Find a line on the fault plane that is the locus of all poles that will rotate the trace of one portion of each faulted stratum through angle *p*, so that it falls on the trace of the other portion of the stratum. The intersection of these lines therefore gives the desired position of the pole.

Construction.—Both portions of a faulted stratum are completely known, when we can determine the fault plane traces of both portions, the strike and dip of one portion of the faulted stratum, and the total heave. The strike-line of the second portion (*A′A′*, for example) is determined from the above data as follows: traces *At* and *A′t′*

(these have been rotated into the horizontal position) intersect at a, and a pole therefore at that point will rotate At so that it falls on $A't'$ extended, the amount of rotation being equal to p. A second point k is found that will also rotate At into the position $A't'$, and these two points locate the line containing every point about which At can be rotated through angle p, so that it will fall on $A't'$ extended. (The easiest construction for obtaining this line is to draw arc rs with a as a centre. It is easy to show that the line through rs is parallel to the line of poles through a.) Every pole will pierce both the fault plane and auxiliary plane at a definite interval when the latter planes are rotated into the horizontal position. For example, the distance between points e and f becomes interval fh after both planes are rotated into the horizontal position. Making $p'p_1 = fh$, the line of the intersection of the A poles on the auxiliary plane becomes ll. MM and mm and NN and nn are the corresponding lines of poles for BB and CC. Projecting AA until it cuts ff at i, and drawing a_1t_1 parallel to at, and from a_1 drawing a_1t_1' parallel to at', the point j where this latter line intersects ff is a second point on the strike-line of $A'A'$ locating the same.

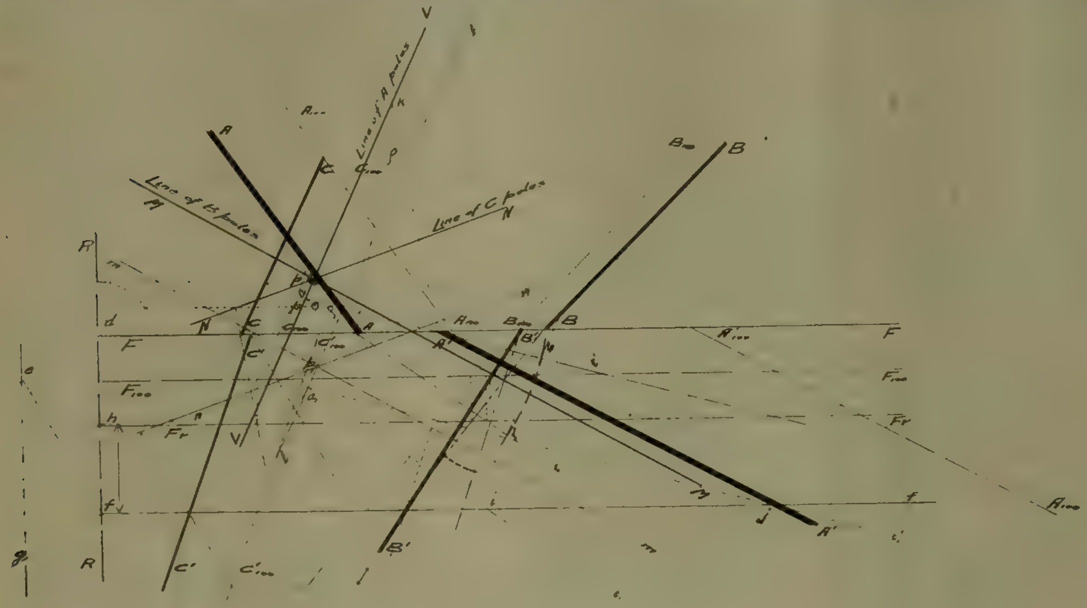

Fig. 15.

The intersection of the lines of poles at p' locates the point at which the desired poles of rotation pierce the parallel plane when the latter is in the horizontal position, and p is the projection of this point when the fault plane has been revolved back into its original position.

Discussion.—It can be shown that if a number of strata have been affected by the same set of combined translatory and rotary fault movements, their lines of poles, determined under the assumption that the movement is of pure rotation, should intersect in a point. As already suggested, this point locates what may be termed the 'equivalent pole' about which an angular displacement, as shown by the rotated fault-plane traces, will produce the same result as the actual successive movements have done. This concept of an equivalent pole may be used in investigating the question whether a portion of the fault movement antedates the formation of the younger stratum. Further application, however, can hardly be covered by simple type solutions. For instance, if it is found that angle p, determined by the intersection of the fault plane traces of the two portions of each stratum, is not constant, it may be necessary to use the data collected during a geological investigation of the area to determine whether the observed structure was the result of rock flowage taking up a different portion of the movement for each stratum, or whether a portion of the rotation took place before the formation of the younger stratum. Or if the angle is approximately constant, but the line of poles does not intersect, this may be due to a translatory movement antedating the younger stratum, or to varying rock flowage. Of course the smaller the area involved in the study, the less the effect of changing rock flowage, and the less complicated the problem.

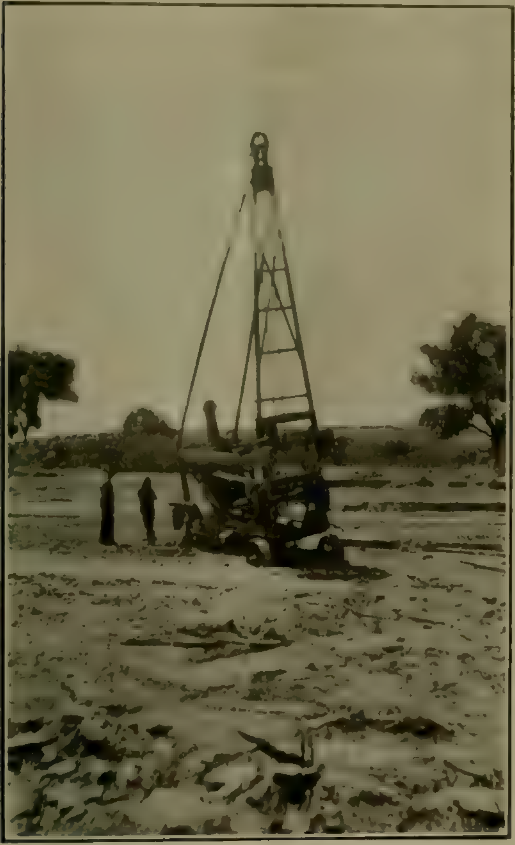
IN driving an intake tunnel, in 1906 and 1907, from the power plant of the Central Pennsylvania Traction Co., at Harrisburg, Pa., to the Susquehanna river, a distance of 1100 ft., it passed through limestone and was from 5 to 20 ft. below the river level. In sinking the midway shaft and driving the headings for 200 or 300 ft. each way from the shaft, H_2S gas was encountered in such quantities as to cause serious inconvenience to the men, and for a time artificial ventilation was necessary. The gas affected the eyes, and the men required frequent medical attention; occasionally their eyelids were swollen so much that their eyes were entirely closed for a day or two. The tunnel passed directly under the yard of the Central Iron & Steel Co., and near two blast-furnaces, and the gas was attributed to the furnace-slag filling which was used extensively around the yard of the steel works. At Cripple Creek large quantities of nitrogen gas exist in the stoping ground and when the barometric pressure is low finds its way into the working places, often causing work to stop temporarily.

THE process of making sand-lime brick was invented in Germany, where it probably has had its greatest development. Observations made there seem to prove that sand-lime brick is a building material which will resist soot. Three years ago an inn was built in Greifenhagen, in which sand-lime brick was used for everything but the lining of the chimney flues, which were built of common brick because at that time the question whether sand-lime brick was equally resistant to fire had not been settled. In spite of the fact that lignite briquettes were burned, soot was found in the flues in a short time, and the flue bricks were permeated as high as the rafters of the ground floor. When the flues were pulled down it was found, however, that the sand-lime brick were entirely unharmed and white in color, in spite of the fact that the brick walls were only about 4½ in. thick. If this experience is repeated elsewhere, it is stated, the fact will be established that sand-lime brick is the best building material to withstand soot.

Prospecting for Gold on the San Juan River

By Robert Livermore

In the summer of 1900 I was engaged to take charge of an outfit to prospect the sands of the San Juan river, in southern Utah, in the hope of finding gold deposits of sufficient value to justify the installation of a dredge. The outfit, consisting of a No. 3 Keystone drill, with the necessary pipe and equipment, was unloaded from the cars at Mancos, Colorado, and after being set up was started out under steam. Bluff City, Utah, a Mormon settlement on the river some 90 miles away, was to be our destination and future headquarters. A fair road for the first 20 miles to Cortez, Colorado, and for 20 more down McElmo creek, by pleasant fruit and alfalfa ranches, made fairly easy going, but from there on the vicissitudes of traction progress were such, from bad roads, alkaline water, and almost impassable sandy 'washes', that at the Yellow Jacket wells, where it was necessary to leave the settled country and make a forced march across 20 miles of waterless desert, a council of war resulted in abandoning the aid of steam and falling back on that of fourteen good horses, recruited from our supply wagon and from ranches along the route.

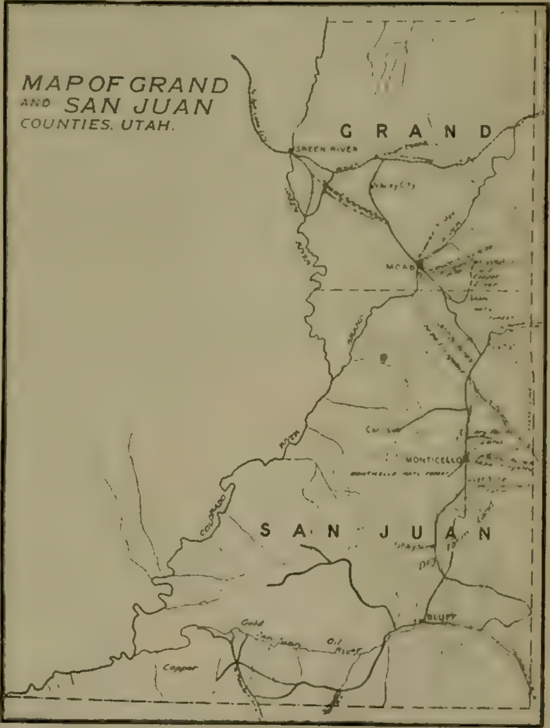


BAD GOING.

We progressed 10 miles into the desert the first day, and there I sent the horses back to water and camped with the drill, undisturbed except by a wandering Navajo and his squaw, who stopped to ask in Spanish a few wondering questions, and to beg a little food, and then vanished in the dusk, doubtless much perplexed at the strange ways of the white man. A steady pull the next day brought us to the broad valley of the San Juan, and camp was made upon its banks, where ample water and green grass refreshed our weary stock, and a cool swim in the river and a plentiful camp supper helped us to forget the discomforts of desert travel. Ten miles of sand along the river, through green cottonwood groves, and under towering sandstone bluffs, brought us near Bluff, where another camp was made, and early the next morning we pulled through town, escorted by fully half the population, and by noon were drilling our first hole on the broad flats below the settlement.

AT WORK DRILLING.

Bluff City and its surroundings merit a short description. Here, remote from the conveniences of civilization and from markets, the Mormons, who, whatever their faults may be, are certainly good colonists, established a settlement some thirty years ago, and by their industry built up a most thriving little community. The first settlement was made some eight miles above the present site, but a great flood swept away their houses and covered their fields with sand. Nothing daunted, however, they built anew the present site, and now have a thriving town of stone houses, pleasant shade trees, and beautiful orchards. Beyond the town lie the fields of alfalfa and corn, watered by a good ditch kept in order by their common labor. Above them tower the steep bluffs which give the town its name, and across the river lies the Navajo reservation, with whose inhabitants they have friendly trade.



The cliffs along the river abound with most interesting remains of the old cliff dwellers who once inhabited the valley and pastured their flocks along the river banks. There are no large ruins, such as the famous cliff palace at Mesa Verde, but there are many well preserved single houses and small villages, perched in nearly inaccessible caves in the cliff faces, with rude steps cut in the sandstone, by which the dwellers reached their homes, still visible. On the smooth rock faces are numerous examples of picture writing, remarkably clear, and drawn with a good deal of skill; one large rock in particular, some four miles below Bluff, is fairly covered with well executed drawings of men, goats, snakes, and various mystic signs. Among the most curious carvings is that of a man shooting, with bow and arrow, a running deer, in which the arrow's course is shown as a straight line, running from the bowman's hand to the deer's heart. Another very curious and often pictured figure is that of a man with goat's horns playing a pipe, or else a goat, upon his hind legs, with the same musical instrument. It seems a curious suggestion of the old Greek Pan.

What manner of people the cliff dwellers were, how they lived, and how they died, is a most fascinating subject, and one which was of great interest to me in the intervals of work; but it is hardly of professional interest. I cannot leave the subject, however, without a mention of one ancient settlement which a companion and I happened upon by chance in the trip across the desert. We were riding some miles ahead of the main outfit, and had exhausted the water in our canteens. My companion had heard of a good spring of water said to exist in a cave in one of the gulches, a mile or two from the road. Upon recognizing the gorge from descriptions received, we rode up the dry and rocky stream bed to its head, and there were well rewarded for our pains. A great cave encircled the head of the gulch, and in the smaller crevices were built the houses of the ancient denizens. Perched on a great rock overlooking the surrounding mesa was a round fort or watch-tower, strongly and carefully built of rock. This tower was very well preserved, even the ends of the cedar joists used for floor beams still showing in the walls. Far back in the largest chamber of the caves was a beautiful clear spring, the seepage water of which had caused a luxuriant growth in the soil of the gulch below.

As we sat in the shady cave, enjoying the cool water and looking out over the green little amphitheatre, we pictured to ourselves the busy life that had existed here so many years ago. Above in the watch-tower had been the sentinel looking out over the mesa with its pastured flocks, alert for alarms; below, the village about its daily tasks; goatherds passing out with their flocks; laborers to the fields; water carriers with gaily colored jars, whose fragments now lay here scattered, waiting their turn at the spring, and all the other life of a prosperous tribe, now gone forever.

The company for which I was prospecting had options on several miles of territory above and below Bluff, and wished that summer to definitely ascertain whether the preliminary work would justify further systematic exploration and the eventual construction of a dredge. I therefore planned to drill as many holes as possible in the short time available, to get a general idea of the conditions, and later, if warranted, to block out the ground systematically. During this examination only the preliminary holes, some twenty in number, extending for about five miles along the river, were drilled.

Near Bluff the valley is a mile or more wide, and in times of flood the water covers more than half of its width. The banks, on which are the houses and fields of the settlers and the 'hogans' of the Indians, are of loam underlain with sand, and, were they of sufficient value, would be ideal for dredging ground. Bluff was the scene of a gold excitement in the eighties, when many a weary prospector footed it back to the railways after it had been found that the profitable placers were decidedly limited in number and extent. At various points along the river I believe that attempts were made to extract the gold by mechanical means—with what success I could not at that time learn—but I believe that my outfit was the first to explore by modern methods the river flats for dredging ground.

Drilling in a country as far remote as this is somewhat more complicated, and necessarily more expensive, than in a settled country, such as California, where good roads abound, machine-shops are handy in case of a breakdown, and labor is plentiful. I found it necessary to establish a camp near which several holes could be drilled; then to move, usually some two miles, to the next place. The expense and labor of moving was greatly increased by the fact that the main drive pinion was so badly worn by sand on the trip in that, upon our first attempt to move under steam, the teeth were ripped off, and not having foreseen such a contingency, we were forced to depend upon horses for the rest of the summer. The horses available were good, bad, and indifferent, mostly the last, and as the sand was unusually deep, a good many of them were required.

In places we found quicksand, so that much time was lost in corduroying roads in advance of the machine; and in spite of all precautions we were more than once badly bogged and had to extricate the drill by a process of plank laying, jacking up, and repeating, till at last a firm bottom was found. In one move across a branch of the river, we made a very firm road by the simple process of riding to and fro until what had been a very dangerous quicksand became firm enough by the continual pounding to afford a splendid crossing. The illustrations show some of the difficulties.

Our crew was as follows: One engineer, one fireman, myself as panner and weigher, a man and team to haul water and fuel, and a camp cook. I kept from two to four Navajo Indians busy chopping wood for fuel for two weeks. These made very good workmen, and did more work at a dollar a day than many self-styled workmen I have met since did at three. The moving, about once every two days, required a varying number of horses, sometimes as low as four, and as high as fourteen. The actual drilling, as figured out from my notes, cost $1.70 per foot, including all wages, food, chopping, fuel, and water hauling. The cost of moving came to about 50 cents per foot, making $2.20 in all, or about $900 for the 20 holes drilled. The cost of the expedition, allowing for depreciation on the drill (about one-half), freight, moving the 90 miles to and from the railroad, preliminary work, and traveling expenses was, of course, much greater than this. In fact, by far the largest expense of prospecting such a district occurs outside of the actual drilling.

Work was started as early as possible in the morning, and continued, if necessary, to dark. Amusements being few, and unions non-existent, we did not feel it incumbent to quit at the stroke of time. Harmony and willingness to work was the rule. The process of drilling did not differ from that usually followed in prospecting dredging ground, and few difficulties were encountered in the actual driving of the hole to bedrock.

The procedure was as follows: The first length of casing was set up in a hole previously dug, and pounded down through the top loam as far as possible by the lugs on the drill stem; then the soil was drilled and pumped to the bottom of the casing. When gravel was reached, the pipe was driven ahead a foot or two at a time, and the drillings pumped out and poured into a wooden sluice box. It was necessary to drive the pipe farther than usual when quicksand was met in order to prevent the sand from running in, but usually the sand and gravel were found to hold quite firmly. Bedrock of soft sandstone was found at an average, and almost uniform distance for all holes, of 17 ft. The character of the drillings showed invariably small gravel and sand with no boulders, and little clay. The drillings from the sluice-box for every two feet were rocked down in a 6-ft. smooth-bottom rocker, the concentrated sand panned, and the gold taken up with quicksilver, parted with nitric acid, and weighed. In calculating results per cubic yard, I used the factor 0.27 for a 6½-inch (outside) casing.

My notes show that the gold was very fine, in fact, much of it 'float' gold. It was about evenly distributed through the sand and gravel to bedrock, with no perceptible in-

[illegible] on the dredge. A sample page from the log reads as follows:

Hole 16.

Began Aug. 25, 1:45 p.m.
Finished Aug. 26, 8:45 a.m.
Drilling 6 hours.
Repairing 1 hour.
Moving 2¼ hours.

Situation: About ¼ mile E. of No. 15 on river bank in cottonwoods. Big drill house on Navajo side bears S. 42° E. ¼ M. Paint Bluff bears N. 42° W. ¾ mile.

Surface—10½ ft. mud, sand, and gravel, no colors.
10½ to 13 ft., gravel, 1 color, 2 specks.
13 to 14½ ft., gravel, 4 colors.
14½ to 16 ft., sand, 2 colors, and float gold.
16 to 18 ft., sand, 10 small colors, and float gold.
18 ft., bedrock, soft red sandstone.

Notes—Gold very light, with tendency to float. Surface water 4½ ft. Bent derrick brace, 1 hr. repairing. Moved to No. 17 with 10 horses. Stuck once in quick; had to jack up. No wood, no water, till late. Built road and did not drill rest of day.

ANCIENT CAVE DWELLINGS.

It is reasonable to suppose that the San Juan river flowing, as it does, through the richly mineralized mountains of the same name, might well contain in its sands sufficient gold to warrant the construction of a dredge. Whatever may be the value of other parts of the river, the results obtained over the ground I drilled did not encourage my employers to proceed further, and I was instructed to pull out. On the return trip the movable parts of the machine were knocked down and loaded in wagons. The whole undertaking was contracted to the Bluff people, and the rig arrived in Mancos in due time at moderate expense. There, the drill was set up again and housed for the winter, and the crew disbanded. I have examined some fields since then, both with the aid of a drill and without; but count this as one of the most interesting in incident, if not in financial results.

Filling in Maps

By [illegible] A. Sperry

Though the method of filling in topographic maps by the use of photographs is known by many engineers, it is surprising that its details are so little understood and that use so seldom is made of it. It must be admitted that it can not be employed in all cases, but, on the other hand, there are many in which it is of great value and assistance, especially to individual engineers or small parties working on a short time allowance in the field.

As in all topographic work, the first step is the establishing of a system of triangulation, the extent of which depends entirely on the needs of the case, and must be left to the judgment of the engineers. As the results of the work from the negative depend strictly on the focal length of the lens employed, it is quite essential that having once determined this value, it be accurately maintained, so that there will be strict uniformity in the negatives. It is therefore advisable to use a camera having a fixed focus, the length of which has been accurately determined by the use of the transit. It is of course possible to use an ordinary camera for the purpose, but great care must be exercised in setting up that the same focus, once established, is used throughout the work. The importance of this will be apparent in the following description and explanation.

An accurate spirit level must be attached, in order to maintain a true horizontal position of the camera. There are two position lines which must be indicated on the negative; one being the true horizon line, the other the vertical centre line of the field. These two lines should intersect at the centre of the negative, obviously at right angles. In case it is found necessary to raise or lower the field of view this must be done by raising or lowering the lens vertically without affecting the level position of the camera. Should this be done, however, a note should be made of the exact distance that the lens is moved from its central position, so that it may be allowed for when the negative is being used. The position of these two lines on the negative may be shown by attaching pointed metallic strips to the inside of the camera, a short distance in front of the sensitive plate, so constructed as to extend into the light rays before reaching the plate and thus causing sharp clear images at the margins of the negative, showing the points between which these line extend. (See Fig. 1.)

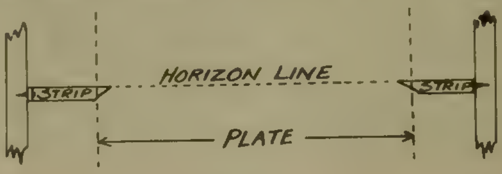


FIG. 1.

This applies to the establishment of the centre line of field also. There are three adjustments which should be determined and corrected. These are: first, the setting of the lens so that its axis or the centre point of field shall be coincident with the centre of the negative; second, the location of the horizon line; and third, the determination of the focal length of the lens. These are given in the order in which they should be made. In the first, it is presupposed that the axis line of the lens is at perfect right angles with the surface of the plate; or, in other words, the front board is parallel to the plate. Sights may be placed with reasonable accuracy on top of the camera on the centre line, for convenience in operation. A sharp, distinct, vertical line should be drawn on the ground glass, through the centre.

Set the camera up and carefully level it. Turn it on some object such as a building, pole, or plumb-line which has been determined to be perfectly vertical. Turn the camera so that this vertical line is in line with the sights along its centre line, always maintaining its position at right angles to the plate. This adjustment will also check the level used on the camera. Having thus fixed the centre line of field, the horizon line should be determined by the use of the transit or level. Set the leveling instrument up at the same height as the centre of the lens of the camera and note several distant objects which are on the same level. Mark the position of these on the ground glass. By drawing a line connecting these the horizon will be determined. Should this line intersect the centre line of field at or very close to the centre of the plate the lens is in proper position. In case there is considerable difference it would be well to raise or lower the lens to bring it to this position, approximately at least.

On these two lines, in the ground glass, construct a rectangular figure as shown in Fig. 2, and the focal length can then be determined. In this figure it is assumed that 5 by 7-in. plates are used, as that size seems to be most convenient for general purposes. The vertical lines at the ends of the ground glass should be carefully drawn at equal distance from the centre line of field; for convenience in operating this distance should be such as to represent an even angle, for reasons given later.

The focal length should be determined by means of a transit, and can be done as follows: Set up the camera over a fixed point, and turn it so as to bring some especially distinct object on the centre line of view. Select some other object on either side and next carefully measure the distance in inches between as shown on this ground glass. Make a number of these measurements, so as to check thoroughly. Take down the camera, and set the transit on this same point. By using the object noted as being on the centre line of view, as 0° the angles of the various objects noted and measured can be determined.

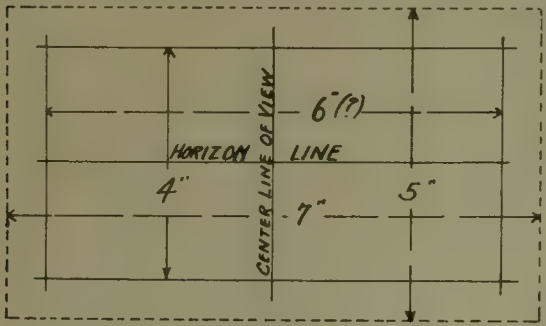

FIG. 2.

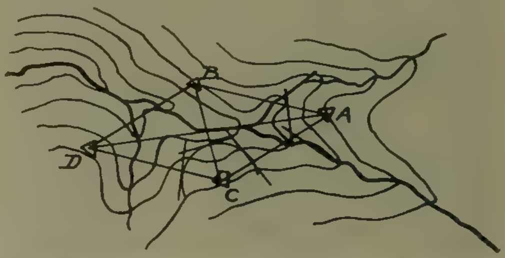
By the method of similar right angle triangles the distance from the focal centre to the plate can be readily determined. For example; the distance from the centre line of view to an object is 2.65 in., and the angle subtended is 16°25′, we have the equation tan. 19°25′ : 2.65 = rad. : 7.25, which is the focal length as employed. To fix the vertical lines at the ends of the ground glass at a point representing an even angle, as mentioned above, we would have tan. 19°25′ : 2.65 = tan. 20° : 3.04.

The camera is now ready for work in the field. After having established the triangulation system, as indicated, with the location of the viewpoints as advantageous as possible, the various sets of views can be taken. Some judgment should be exercised in the orientation of the views. In each set some one of the views should be so directed as to show one of the other viewpoints on the centre line of field, as this will add materially to the convenience in platting. The following sketch will serve to illustrate. At point *A*, the middle view of the set of three plates will have point *D* on the centre line, and so on. The special reason for this is that in determining angles with the centre line as the 0° point, the line *A D* of known bearing will be the basis, thus simplifying the operation.

The adjoining views should lap at least one-half inch, as at that point the objects will be clear and distinct, and also this will allow a margin in case of injury to the emulsion in development or manipulation. After taking the first view, some prominent object should be noted on the vertical line at the end of the ground glass, toward which the camera is to be swung. Swing the camera so that this object shall coincide with the line at the other end and thus make a swing equal to the angle subtended by these two lines. As indicated above it would make for convenience to have these lines include some even angle. By repeating this operation the full set can be taken with a systematic relation between the negatives.

By calculating on the negatives the angles between points, of which the angular difference has been previously determined by the transit, the work of the camera can be carefully checked. Should there be a persistent difference between them there is reason to conclude that the focal length of the line has not been correctly computed, and correction should be made. Negatives made for this purpose should be developed denser than usual, in order to bring out all details sharply and clearly, for on this depends the value of the work, namely the amount and clearness of detail to transfer.

In order to readily work from the negative it should be held at an angle of from 30 to 50° from horizontal according to personal preference, so that a clear white diffused light may be transmitted. This is accomplished by the use of a stand similar to the retouching stands used commonly by photographers. The negative should lie, emulsion side down, on a ground glass on which two lines are drawn at right angles to each other. The negative is so placed that one of these lines is coincident with its horizontal line, and the other with its centre line of field.



SKETCH SHOWING ARRANGEMENT OF VIEWPOINTS.

It might be well to state at this point that neither films nor prints should be used for this purpose, as both are liable to distortion. Glass plates should be employed, as they preserve the proper proportion and relation perfectly.

After having located the triangulation points on the paper on which the map is to be made, a circle with a radius equal to the focal length of the lens should be accurately described around each point of view. This circle represents the section of a sphere with which the plane of view (the negative) comes in contact tangentially at the point of intersection of the centre line of field and the horizon line. It is, of course, perfectly vertical. If, as suggested, one negative of the set has been taken with some other triangulation or view point on the centre line of field, and consequently having a given bearing, the position of this negative can be readily fixed by drawing a line at right angles to the given line, and tangential to the circle. If this has not been observed it will be necessary to determine the angle between the centre line of field and the given line, and by laying off another radius on this angle the 'negative plane' may be located by drawing a line tangential to the circle at the point cut by the new radius.

By using a properly constructed lens all vertical lines are parallel at all points of the negative. As a consequence all horizontal angles are determined by measuring the distance from the centre line of field, and using this distance as the tangent of the angle with radius equal to the focal length of the lens. Were the sphere alone considered there would be a convergence of these meridians, or lines of equal azimuth, to the pole of the sphere, but inasmuch as these lines are projected through the surface of the sphere to the 'negative plane' this convergence is overcome, and they become parallel. This is desirable to [illegible] demonstration of which will not be entered into in this paper. To illustrate, in moving from the centre line of field to a line that an object is 2.25 in. distant. Assuming the focal length of the lens to be 7.52, we have the following equation: 7.52 and 2.25 = tan. 20°39′.

With the vertical angles the case is different. While the horizon line is perfectly straight and continuous in all the negatives the imaginary lines at given elevation angles are not parallel to it in the negative. As before, only in reverse, if the sphere were considered only, these lines of latitude, as it were, would be parallel, but as they are projected to the 'negative plane' there is obviously a divergence. To illustrate: in the view shown, the horizontal lines are all normal to the vertical lines. On the centre line of field all angles of elevation or depression will be calculated in the same manner as angles of deflection. This is because the initial point of the angle is located at the point of contact between the sphere and the 'negative plane.' Thus the roof line at its intersection with the centre line of field will be computed by measurement of the distance from the centre line of field, this distance being used as the tangent reduced to the simple radius of the sphere.

In computing the angle of elevation of the point in the roof line at the end of the building, however, a new set of factors enter. While the point on the roof line at its intersection with the centre line of field is directly above the point of contact between the sphere and the negative plane, or the centre point of field, the point at the end of the roof line is directly above the outer end of the secant of the horizontal angle between the centre line of field and this point.

As the actual distance between the horizon line and the roof line is constant at all points, and as the secant of the horizontal angle must be used as the radius of the new angle, it is clearly evident that the elevation angle of any point outside the centre line of field will be in inverse proportion to the secant of the horizontal angle between it and the centre line of view. Thus the rule for determining the vertical angle of any object may be stated as follows: The tangent of the angle of elevation (or depression) of any object in the negative equals the vertical distance from the horizon line divided by the focal length into the secant of the horizontal angle between the centre line of field and the object. To illustrate: supposing the focal length to be 7.52 in. as above, the object 2.25 in. from the centre line of field and 3.15 in. above the horizon line. The horizontal angle has been determined at 20°39′ by the equation $\frac{2.25}{7.52}$ = tan. 20°39′. The natural secant of 20°39′ = 1.064. The radius or focal length = 7.52. 1.064 × 7.52 = 8.00 or the actual secant. This being used as radius the angle and the vertical distance as the tangent of the vertical angle we have the following equation:

$$\text{tan. X} = \frac{\text{vertical distance}}{\text{focal length} \times \text{nat. secant of hor. angle}}$$

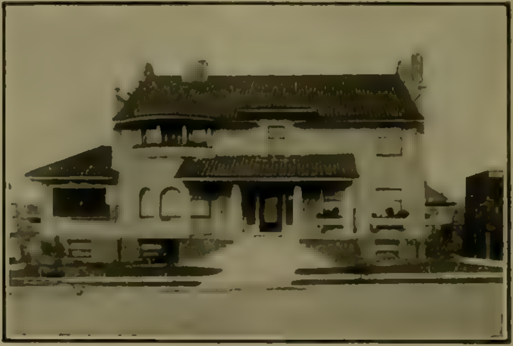
or $\frac{3.15}{1.064 \times 7.52}$ = 0.39375 or tan. 21°29′, the angle sought.

Only the horizontal angles are transferred directly to the plat, the vertical angles being used only for the computation of elevations of objects after their location. After having calculated a few important angles so as to thoroughly locate the positions of the various negatives the mass of the information can be transferred by simple measurement. The position of each negative of each set should be shown by a line drawn tangential to the circle at its proper point. Each negative should have a number corresponding with that of the line.

By placing a scale graduated to $\frac{1}{100}$ of an inch so that the 0 corresponds with the centre line of field a common triangle may be run along the ledge on which the negative rests, and the distance of any object from the centre line of field read off at once in inches and hundredths. As the line representing this negative is in exact correspondence on the plat, it is clear that the direction line passes through the negative line at the same distance from the radius to which it is tangential in the plat. Note the distance on the negative line and draw a line through it from the centre of the circle or the point of view. The line of direction of this same object from some other point of view is likewise determined, and by protracting them to intersection the position is shown. A third line, from still another point of view, will check it. This process can be carried on indefinitely.

In determining elevations by the vertical distance, the tangent of the angle of elevation or depression into the distance of the object, as indicated on the plat of course, gives the relative elevation above or below the centre of the camera. After calculating the elevation of a number of prominent objects for checking purposes, the mass of detail may be more roughly determined, if it is so desired, by the use of a diagram made on a thin sheet of transparent celluloid, the lines on which show the curves of equal angular elevation. This diagram should be made for the focal length of the lens employed in each case. By using the formula, vertical distance for a given angle of elevation = tan. A × (focal length × secant B) in which A = the vertical angle assumed, and B = the horizontal angle from the centre line of field at which this vertical angle is taken, these curve lines may be constructed at as frequent intervals as may be desired.

By laying this diagram under the negative with the centre lines of field and the horizon lines coincident, the angles of elevation or depression of the various objects and points may be very closely read by interpolation, and from these the elevations readily calculated. In the selection of a lens for this purpose it is not advisable to choose one of a much wider angle than 60° on a 5 by 7-in. plate. This gives good general details and illumination, and is less liable to distortion than those of wider angle. In any case the lens must be perfectly isometric and rectilinear as well as perfectly free from astigmatism. It is hoped that this brief explanation of the use of photography in filling in maps may be of service to engineers in the field.



VIEW SHOWING HORIZONTAL AND VERTICAL LINES.

FOR PRIMARY LEVEL LINES standard Y levels are used by the U. S. Geological Survey; lines are run in circuits or are closed on precise lines, with an allowable closing error. The standard bench marks, which are established by the Survey at different points, are of two forms. One form is a circular bronze or aluminum tablet 3½ inches in diameter and ¼ in. thick, having a 3-in. stem, which is cemented in a drill-hole in solid rock in the wall of some public building, a bridge abutment, or other substantial masonry structure. The other form, used where masonry or rock is not available, consists of a hollow wrought-iron post 3½ in. outer diameter and 4 ft. in length. The bottom is split and spread to a width of 10 in., to give stability, when planted. A bronze or aluminum-bronze cap is riveted over the top of the post. A third style of bench mark with abbreviated lettering is used for unimportant points. The tablets, as well as the caps on the iron posts, are appropriately lettered and stamped with numbers representing the altitude of the bench mark.

Cave-Ins in Oil Wells

By Dorsey Hager

An oil well is producing oil at a steady rate, one it has maintained for several months with but slight variations in flow. Suddenly the well ceases, or almost ceases, to flow. Some trouble has befallen the well, but what this trouble is generally puzzles the oil operator, especially when the rods, tubing, and well pump are all found intact and in good working condition. A bailer or sand bucket is let down in the well by means of a cable. The bailer fails to reach the bottom of the hole. Apparently it has reached a collapsed place in the casing and cannot sink any farther.

The bailer is withdrawn and its contents dumped into a box made for this purpose. Oil and a fine sandy shale constitute the mixture that rushes into this dump-box. Interspersed through this oil and fine shale hard lumps appear, which upon examination prove to be lumps of compact shale. This shale gives the clue to the trouble.

Overlying most of the oil sands of the California fields is a layer of soft, friable, fine-grained shale. This shale roof confines the oil to the coarser grained sand beneath. When this roof caves in it becomes a source of much expense and trouble to the operator. It is generally understood that when a well is first 'brought in,' or first begins to produce oil, it should make large quantities of sand. So general is this belief that a well which produces little sand at first immediately becomes the object of suspicion. The withdrawal of this sand—often 50,000 to 100,000 cu. ft.—supposedly causes the formation of a large cavity in the oil stratum wherein the oil may gather to form a pool. Such a condition is certainly very desirable under some circumstances, as activity of this kind would give a much larger collecting area for the oil than a cavity with but the diameter of the casing. But the oil operators do not consider that the loose sands of this region will allow such a favorable condition to exist for any length of time except under unusual circumstances.

An examination of the oil sands of California proves them generally to be clean, unconsolidated quartz sands. These sands do not form a sandstone, nor will they stand up rigidly like sandstone. Their tendency is rather to flow, especially when saturated with oil. Further, a study of the angle of repose of these sands (the angle or slope at which the sand will lie, due to the friction between its grains), shows that the average value for this angle is a trifle over 11°, or approximately 20 ft. in 100, a grade of 20 per cent.

Consider a typical case. The illustration shows two oil sands, A and B, separated by a stratum of shale. Above A is another stratum of shale, intercalated or interlain with several sandstone beds, each several feet in thickness. Above the top shale is a water sand, W. The oil sands have an average dip of 17 ft. in 100, or nearly 10°. (The thicknesses given in the figure are typical.) Suppose that oil and sand are pumped from the well in large quantities. The remaining saturated sand seeks its angle of repose, the angle of 20 ft. in 100. This angle is greater than the angle of dip of the oil stratum.

Consequently a cavity will occur at the top of the oil sand and around the casing (where the angle of dip is equal to, or greater than, the angle of repose no cavity would exist). The roof overlying this cavity is left unsupported. As this is formed of a soft shale it soon begins to crumble, especially as it is washed by the oil in the pool below it, and affected by the suction of the escaping gas and oil which are drawn upward from the well. The bottom layer of shale, an inch or two in thickness, is considerably harder than the shale above it, and when this layer gives way crumbling proceeds very rapidly. Now any unusual disturbance will precipitate a cave-in or fall of the shale roof. Excessive suction due to swabbing, to a long pump stroke, or to very high pumping speed will create sufficient disturbance to cause a fall.

The cave-in may result in collapsing the casing, in sweeping it entirely to one side of the former hole, or may not affect the casing at all. However, the shale now rests upon the oil sand and totally fills the former cavity below it. As this shale forms an almost impervious cover for the oil sands, no oil will rise into the open casing above the oil sands. In many instances some oil does rise above the shale blanket, though not a very large quantity.

If the casing has not been too greatly damaged it may be brought back to its normal cylindrical shape by means of a swedge, a round-nosed tool, tapering from a small diameter at the nose to a larger diameter slightly less than that of the casing. The nose first enters the injured casing, and as it is gradually driven downward enlarges the opening until the casing regains its proper shape. Now the bailer is introduced into the hole and the shale bailed out, if possible. Generally it is necessary to resort to drilling tools to penetrate the compact shale. The drill-bit loosens the shale, which is then bailed out until oil begins to freely enter the casing. Then the well is put to pumping again. This cleaning-out process may call for a week's time, or for months, depending upon the quantity of fallen shale.

In the figure is shown a sandstone layer, 5 ft. thick, overlying the shale above A. The caving will extend to this sandstone bed, and must then stop, as the hard sandstone will not cave in readily. As this is the case, the shale that has fallen will be like a blanket upon the oil sand beneath. When this blanket-like layer of shale has been drilled through the sand below the shale will furnish oil freely. However, no cavity favorable for the accumulation of oil will exist immedately above the oil sand. Where the fall of shale has not been too great it is possible to clean all the shale from around the casing, but generally this is not the case, as the cave-in extends clear to the sandstone bed near the centre of the shale stratum. Some of the fallen shale may be bailed out of the hole, but the shale, on the whole, forms a compact layer that remains packed around the casing. Danger from cave-ins is now past, but the presence of finely disseminated shale in the oil causes much trouble in operating the well.

The example given above is a general case. There are other speial conditions and cases where cave-ins do more than merely cause a temporary stoppage of production, and require a week or two for treatment. In some instances the casing may be so greatly damaged that it must be replaced with new material. This calls for a period of time generally exceeding a month, and not uncommonly several months. Sometimes the well must be re-drilled. Where a water stratum overlies the shale and no sandstone partings are present to prevent caving, water is admitted to the oil-zone. This may cause the abandonment of the well and endanger the life of a whole field unless some way is found to shut off the water, which is not a simple matter under such circumstances.

We have so far considered conditions favorable for cave-ins. There are, however, several conditions that are unfavorable. Briefly these are three in number. (1) Where the oil stratum consists of a coarse gravel formation; (2) where there is a thickness of several feet of sandstone immediately overlying the oil sands; (3) where the angle of dip is equal to or greater than the angle of repose of the oil sand. The first condition is found best illustrated at McKittrick. In this field some of the oil formations consist of pebbles which are larger than the perforations in the casing. As the pebbles cannot enter the casing, only the fine can do so; the consequence is an oil stratum without a cavity above it. The pebbles act as natural strainers, the large interstices offering free channels for the inflow of the oil.

It is obvious that where a hard sandstone roof overlies the oil sands the cavities below the roof are not likely to cause cave-ins, especially if the sandstone, or 'shell,' is sufficiently thick to withstand the pressure above. Such a condition quite often occurs in the oilfields. A thickness of 5 ft. should insure safety, especially when other sandstone layers occur in the formations above the shale.

The third condition requires that the dip of the oil stratum be equal to or greater than the angle of repose. If the dip is greater than the angle of repose the sand of the stratum will replace the sand that is withdrawn from the well. As a consequence, the cavities will occur around the casing, but will extend at some places upward to the cap and at a considerable distance from the well. The column of oil standing in a well will modify the tendency of the sand to cave in. A column 1000 ft in height would exert a pressure of 100 lb per square inch where the oil possesses a gravity of 22° Baumé.

The present method of perforating casings appears to invite cave-ins. The perforations are generally oblong in shape and vary in size from 1/8 by 3/4 to 1/2 by 1 1/2 in. The large perforations admit sand freely, as this seems to be desired, the perforations serve their purpose. The withdrawal of the sand, however, results in cavities, and, later on, cave-ins, with the attendant expense, trouble, and sometimes permanent injury to the well or oilfield. That these cave-ins can be avoided is unquestionable. The use of strainers or screens, which allow only the finest sand to enter the well, would do away with the trouble so prevalent in the California fields. The strainers consist of lengths of casing with horizontal slots cut in them, the slots having a width slightly less than the diameter of the average sand grain of the particular oil sand.

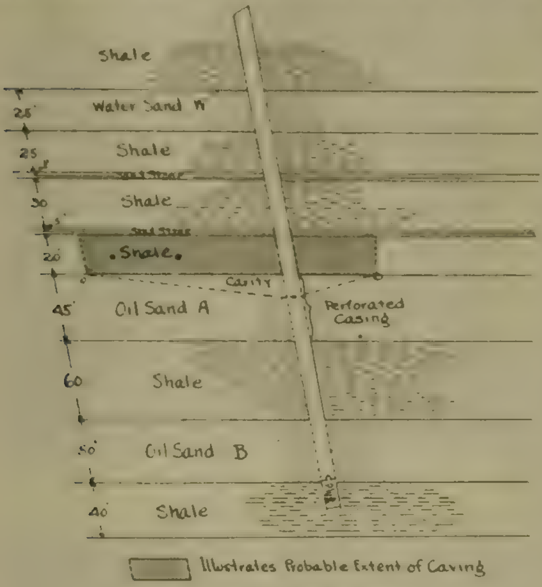


DIAGRAM SHOWING CAVING.

Screens consist of lengths of perforated casing wrapped with wire which is wound spirally around the casing. The width between the wires is slightly less than the diameter of the average sand grains for which the screen is to be used. These strainers and screens can be placed as liners inside the casing, which is perforated according to present methods. However, it is the opinion of many oil-men that strainers cannot be used successfully with the heavy gravity oil of California. There seems no valid reason for this. Strainers are successfully used in both Louisiana and Texas, with sands as fine if not finer than those of this State. Besides some success has been attained with strainers in the Sunset-Midway field. Not only this, but the pores or interstices between the sand grains of the oil sand are not as large as the slots in a strainer, or the spaces left between the wires of a screen. The question, however, is one of economy.

Is it cheaper to have cave-ins with the resulting trouble and expense, and with perhaps a large initial production, than to use strainers or screens and avoid cave-ins? The use of strainers or screens might reduce the initial production of a well, but would guarantee long life and little trouble.

The problems presented by cave-ins are by no means simple. They call for the exercise of thought and effort in overcoming their effects. The prevalence of these evils is so general, the expense of treating them so great, and the results so pernicious that it seems to me that more interest and more careful study should be given the subject than is the case at present. The effects are treated; what should be done is to reach the cause. Practise rather the old adage, "An ounce of prevention is worth a pound of cure," and cave-ins will cease to be a source of trouble.

Hints on Travel in Mexico

By G. L. Sheldon

I have had thousands of miles in the saddle, on the West Coast, and presume that similar conditions exist elsewhere in the Republic. An engineer making his first trip to Mexico is very likely to meet with some discomfort and disadvantages, which can be easily overcome by proper foresight. On leaving the coast—and there are few mines in the agricultural section—there are no roads, only trails, and it is necessary to take to the saddle.

If possible get a letter of introduction to some prominent person or firm at the point where saddle and pack mules must be obtained; tell him what you want, and leave it to him. It is best to see personally that the saddles and *aparajos* (pack saddles) are in good condition, strong, and durable. I once rolled three mules and packs down the mountain several hundred feet, because the leather string which tied the breeching to the *aparajo* was not strong. It broke going down the mountain, frightened the mule, which ran in behind the others on the narrow trail, and threw them all down the mountain. Have this man secure you a good mozo; a foot-man will do, if it is not too long a trip; but if out for any length of time, it is impossible to keep a good man and make him go afoot, as his feet invariably get knocked out. Never take a mozo who is not recommended by some well known man. The mozo is generally under obligations to his patron, and he will do what is right; otherwise he knows he will be held accountable. It is not safe or advisable to make a practice of traveling without a mozo, even if only for a day's trip. Americans who have been killed on the trail in Mexico have generally been alone or have abused their mozo. Some mozos are quite handy at cooking. The usual charge for mozos and for mules is ₱1 per day and expenses. If you are going into the mountains, never take a horse; feed is often poor and scarce, and a mule will do well where a horse will starve; mules accustomed to mountain trails are preferable. When you strike bad, rough, dangerous trails, a mule is far safer, as he is sure footed and careful; you can not force one over a precipice, even in the darkest night. A horse has too many feet; he does not know what to do with them all when he gets into a bad place; and with a spur he can be driven over a cliff at any time. Always wear spurs when riding mules; they have much respect for a spur, even when they care nothing for a whip or quirt. I much prefer the macho or male mule, as he is more quiet and gentle; the mare mules are of a more nervous and treacherous nature.

You will find that you must always pack your own bedding in Mexico. While in the United States buy a large quilt, army folding cot, and have a canvas bag of 8-oz. duck made, 18 in. diam., 4 ft. long, with eyelets for small rope to tie with. Buy your blankets in Mexico; good blankets are cheaper there than in the United States. Fold your quilt double for a mattress, and you have always a good bed, above the ground, away from venomous reptiles and insects. While there are not many of these, one sleeps better and does not get nervous and restless thinking of them. If you are in Mexico during the winter months you will need plenty of bedding, even in the lower country where there is no frost, otherwise you will get chilled through toward morning. There is room enough in your sack to roll up with your cot and bedding an extra suit of clothes, and the whole pack will not exceed 25 pounds.

When going several days' trip, I much prefer to pack provisions and camp out. Feed and water are abundant in the mountains; you will live better and make more miles than if you stop at ranches, as you can get started earlier in the morning. There are many trails in the mountains where one is obliged to camp out, which is possible with comfort and pleasure for nine months in the year on the west coast. Buy coffee, tea, sugar, flour, baking-powder, soda, salt, potatoes, rice, sago, oatmeal, a piece of bacon for the lard, and any canned goods or dried fruit that you wish and can get. It is hard to get fresh meat, except in the larger towns, but you can always get dried meat. Take this and have some woman toast it, and mash it on a *metate* stone, so it will all pick up fine; keep in a clean sack. When on the trail, take a couple of handfuls of it in the morning, put it in the frying pan with enough water to more than cover it, let this boil 6 to 8 minutes. If you have any cold boiled potatoes left over from night before, slice them fine and put in the pan also. Take two teaspoonfuls of flour in a cup of water, stir till thoroughly mixed, put it in the frying pan while boiling, continue to stir, to keep it from burning, for a minute or more, till it thickens. You will relish this greatly, as one always has a good appetite when in saddle and camping out.

Eggs can nearly always be bought cheaply in Mexico. To carry them, buy a couple of morrals made of the maguey fibre by the Indians; they are about 8 by 12 in., with slings of same material to hang over pommel of saddle. Take along some old newspapers, and when you buy eggs at the ranches wrap them well in pieces of paper, put them in the morrall and tie it on the right-hand side behind the saddle. You generally carry your coat tied there; run one end of it through the string of the morral to steady it and keep from pounding; tie up short, and you will have no trouble. I have packed them 150 miles in hot weather and they were all right. With eggs and baking powder fine pancakes can be made; use a piece of bacon or suet to grease the frying pan. You can nearly always get limes, as they grow wild. The juice of a couple, with soda, eggs, and two or three lumps of sugar, make an even better pancake. If you prefer bread baked in the frying pan, use a little grease from the fried bacon, with baking-powder.

You will find the ordinary sample sacks which one buys for 50c. per dozen in the United States, just the thing for many of the provisions; a separate sack for each is best, then put all in a strong large sack for the pack. Don't pack heavy boxes for grub; it is not necessary, and as they begin to get empty the things will pound to pieces. For your kitchen, take a couple of 6-qt. pans, one for a wash dish and the other for bread-pan; place your frying pans in these, your plates in the frying pans, on top of the plates a large kettle, with two or three small ones nested in it, and cups in the smaller. All these dishes should be of granite ironware, which can be bought nearly everywhere in Mexico. Put a coffee pot on top, and wrap up your kettles and frying pans with newspapers or old cloth, as they get black in the fire. In this way things will be kept clean and from rattling on the trail; if you have trouble from this tuck in some palm leaves. Knives, forks, and spoons should be wrapped in paper or cloth and put in a common jute ore-sack; tie down tight, then put this sack into a heavier and longer strong sack. When you have your pack all cinched on, except the last or left-hand hitch, place your kitchen on top in the middle, tuck the top end of sack down under cinch rope from in front, double back over in the middle and cinch tight. Half-hitch and tighten the pack at the side, throw the rope over the top and around the cinch rope at opposite side, then back over to left side, behind, and tighten, but not so much as to injure the dishes. You will find it will ride all right and gives no extra weight to pack. Caution the mozo to be careful when the mule gets out of the trail, so that he does not knock the pack off under low branches of trees. I have packed dishes in this manner for years and they are still in good condition. A piece of canvas, 3 or 4 ft. square, spread on the ground makes a good table-cloth.

Be sure and get corn for your mules when passing some ranch during the day, put it in a sack and pack it on top of the cargo; you will find it at nearly all ranches and they will always sell to a traveler, just as they will always keep one over night. You are never turned away from a house in Mexico; at the poorest peon's or the rich haciendado you are made welcome to the best they have, and it is often hard to pay for it. Whenever they leave it to you to set the price, always pay what is fair and right, neither too much nor too little, but the customary price. Give your mules corn both night and morning; they will eat more when fed at night, but they are not nearly so apt to stray off. The morral makes a good nose-bag to feed them in. Put a small cowbell on the lead mule, and have the mozo take them to a place in advance of you, so that if they return during the night they will pass near you, as they will take the same trail back they were driven out on. Nine times out of ten the bell will awaken you, and the mozo can get up and drive them back; he will do this no matter how dark. It is best to always see personally that the mules are fed. When traveling it is best to lead and have the mozo keep the pack animals up with you; you will travel as far in a day, and if there is any accident, or the mozo needs help with the packs, you are there. When you go ahead and leave the mozo he may stop to visit or loiter on trail, then later run the mules to catch up, and your mules will soon be sore-backed.

If you do not pack to exceed 150 lb. on a mule, they will easily keep up with you; traveling in the mountains 25 to 30 miles per day, or in the level country 40 to 50 miles per day. Nine to ten hours in the saddle, day after day, is enough for man and beast. Take off the packs and saddles at noon and loosen up the cinches of *aparajos*. Just a lunch at noon and a short rest is sufficient, then camp earlier at night. Be sure and take plenty of small change with you to buy corn, eggs, fruit, fodder, etc., as it is almost impossible to make change at the ranches; if you cannot make change, you cannot buy. Of course, if you are only going a two or three days' trip, you do not want to bother with a lot of provisions; but even then you should pack some coffee and sugar in your morral.

When depending entirely upon the country, a visitor from the United States not accustomed to hardship is pretty apt to be disgusted; then nothing will look good to him, and he will probably not invest. By all means feed him well, take good care of him, and if you have anything of merit, you can interest him. Many a deal has been lost by not properly attending to such details. I once took a millionaire, who weighed 220 lb., and had never been on a mule, nor on a horse for 40 years, on a 6-day trip into the mountains, camping out. We made the deal and the return trip with satisfaction to every one; the investor said he enjoyed it and had had the best time of his life. Don't get angry at your mozo and swear at or strike him, as it does no good, and is only an injury to yourself. Don't expect too much of him; remember that you only pay him 50c. per day. It is both proper and wise to speak the time of day, or *adios*, when you meet natives on the trail; and it is necessary to always pass to the left when you meet in Mexico.

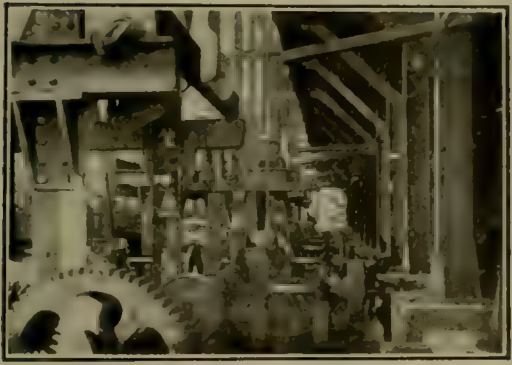
THROUGHOUT the coast region of British Columbia deposits of magnetite are found which are high in iron and low in phosphorus. These deposits occur at the contact of igneous intrusives with some sedimentary rock, usually limestone. The deposits are very irregular in their outcrops and nothing definite as to the size and shape of the orebodies can be predicted. They belong to deposits of the pegmatite type, and presumably have a greater extension in depth than in either breadth or length. Usually a series of outcrops is found along the line of contact, varying from a few square feet in area up to deposits 150 ft. wide and several hundred feet in length. Little is known as to their depth, though several deposits have been opened by adits to a depth of 100 ft. At the Paxton mine on Texada island the ore is exposed by a tunnel for a width of 75 ft., at a depth of about 500 ft. from its highest outcropping on a hill above.

Recent Developments in Diamond Mining

By C. A. [illegible]

There has, within the last few years, been a distinct revival of interest in diamond mining, and a great deal of prospecting has recently been undertaken in various parts of the world. Discoveries in Africa have been particularly abundant. When in Amsterdam and Brussels, some weeks ago, I was informed of a number of good finds that had been made near Lake Tanganyika in the Haut Katanga country, which is now being opened by railroads from both the south and west; and also in German Southwest Africa, Rhodesia, and provinces of the Union of South Africa. Exploration is, furthermore, being quietly carried on in the southernmost districts of the Congo State, in the interest of a French-Belgian syndicate, and some interesting developments have already resulted. Meanwhile minor operations in Brazil, Arkansas, and other parts of the New World, and isolated finds elsewhere, are sufficient to lead to further activity, which will result in a considerable extension of the industry. The following may, therefore, be of interest.

WASHING PANS, GRINDING MILLS ABOVE.



DRIVING MECHANISM OF MILLS.

In the early days of diamond mining the material in which the precious stones were found was hoisted from the pits and sent to what were known as 'depositing sites,' where it was spread out in a layer 12 to 18 inches thick and allowed to weather so that the blue ground or hard rock composing it would disintegrate. This, however, took about six months for its complete accomplishment, and not only kept a great deal of capital idle during that period, but also afforded opportunity for the theft of many of the larger stones, no matter how carefully the sites were guarded.

Of recent years, therefore, there have been installed what are known as 'direct-treatment' plants, of which those operated at Kimberley, in South Africa, by the De Beers Syndicate, are the most notable. Here the material, as mined, passes through gyratory breakers, of standard Gates construction, and is reduced to about $1\frac{1}{2}$-in. size. Thence it is delivered to trommels, which screen out all material larger than $\frac{1}{2}$ in. The oversize goes to light crushing rolls, set with $\frac{3}{4}$-in. gap, and their product, after again being screened, is sent with the fine from the first trommels to washing pans.

GRINDING MILLS, VOORSPOED D. M. CO.

ELEVATORS AND GENERAL VIEW OF ARRANGEMENTS FOR GRINDING AND WASHING.

These pans are one of the most interesting features of diamond mine equipment. They are constructed with the object of forming a thin sludge, too thin to carry any diamonds, but thick enough for the overflow of lighter minerals. As the constant agitation in the pans tends to break up the particles of clay, the diamonds are exposed, and the clay and other light material is washed over into the discharge.

The revolving mechanism of the pans consists of stirrer arms, fitted with blades of steel which clear the bottom by about 1 in. These are so designed that their action continually shifts the heavy material, which drops to the bottom of the pans at the outer edge. For this purpose the stirrers are arranged in spiral form. The feed is introduced at the periphery of the pan, so that the line of its entrance is at a tangent, and the discharge is through a small hole, about 1½-in. diameter, at the bottom of the pan.

The material recovered consists of a variety of minerals, including garnet, olivine, and other stones, in addition to the diamonds. Further concentration therefore becomes necessary. For this the first step is jigging; but, owing to the small difference in specific gravity between diamond and garnet, for example, the separation made by this means is not very close. After passing the jigs the product is either sorted by hand or else is allowed to flow over greased tables.

The greased table is an invention of George Labram and consists merely of a feed-box with a table, below, which has a riffled top. On this grease is smeared about ½ in. thick. The action of the table is based on Labram's discovery that garnet and olivine have no affinity for grease, but that diamonds, the moment they touch the greasy surface of the table, will stick. After a certain quantity of concentrate has been allowed to pass over the table, through the use of a liberal volume of water, the grease is removed, heated, and run off, leaving the diamonds in the bottom of the vessel. After this, the diamonds are boiled in sulphuric acid, to remove dirt and impurities, and then sorted.

The De Beers Syndicate has introduced an innovation in the final stages of diamond recovery, by putting the product of the jigs through a process of magnetic separation. This is kept strictly secret, so much so that even directors of the Syndicate have been refused admittance to the mill, which is always kept locked. It is, however, stated on good authority that a modification of the Wetherell process is used, under patents which the De Beers Syndicate controls.

One great advantage of magnetic separation is the fact that it dispenses with the use of a large quantity of water, which, despite the efforts to conserve the supply by using it over and over again, is a serious problem for a hot, dry country, where the losses from evaporation are so great. The accompanying illustrations were secured at the plant of the Voorspoed Diamond Mining Co., where the blue ground is harder than that of the De Beers deposits, and a different process is used in the initial stages.

After crushing in gyratory breakers, the material is delivered to special mills, which are similar to the mills used in ore reduction, taking the place of crushing rolls. They consist of two heavy rollers, with chilled iron treads, revolving on a manganese-steel pan having 1-in. perforations in the bottom. The rollers do not ride on the pan, but are provided with a check which is set so that they come within no more than ¾ in. from the perforated plate. The material fed to these mills is crushed fine enough to pass through the holes at the bottom, after which it is delivered by gravity to washing pans like those above described. From this point the usual course of treatment proceeds, except that the Voorspoed Mining Co. has additional mills placed below the pans last mentioned. These take the discharge from hydraulic separators and grind it for further treatment in the pans. The separators are set so as to have an underflow of material, say ¾ to 1 in., as there are very few diamonds of this size, and they find that it pays to grind that fine. In former times, when richer deposits were being worked, diamond mining companies were afraid to do this, for fear of crushing diamonds of great value; but the system now is to offer a bonus for the finding of large stones, and, owing to the number of hands through which the material passes, any such are almost always found by the native 'boys' before reaching the crushing rolls or grinding pans.

It is, of course, well known that careful precautions are taken against the theft of rough diamonds by the men employed in the mines; but few Americans probably realize how rigidly they are watched. The natives, who have the best opportunities of coming in contact with the stones, are kept in compounds, which amount to prisons. During their entire time of service they are not allowed outside of these compounds, when off duty, and upon leaving the company's employ they are subjected to a most searching examination, both inside and out, cathartics being freely used. Upon arriving in the detention compound, they also have two great pieces of stiff leather padlocked on their wrists, so as to prevent them from using their hands in any way, and these are not removed even at mealtime. For the week of their stay, they are fed by attendants. Despite these excessive precautions, however, there is still a good deal of illicit diamond buying going on in South Africa.

For the photographs reproduced herewith and the facts relating to equipment, I am indebted, through a friend, to Edward L. Bateman, of Johannesburg.

Control of Thermal Operations

By G. K. Burgess

*The past ten years have witnessed great strides in the development of the manufacture and use of pyrometers. Formerly the question usually asked by an engineer responsible for the control of some process involving change of product or output with varying temperature, was, "Do I need a pyrometer, and is there a reliable one?" Today he knows he needs one, and asks which is the best for his purpose. The Bureau of Standards carries on correspondence with the users of such instruments, endeavoring to furnish them with the information best adapted to each case, although no pretence is made of replying to the often asked question, which is the best pyrometer. In a similar way, advice has been furnished to universities and technical schools regarding the formation of courses of instruction in heat measurements, the installation and design of new apparatus, and the testing with the highest possible accuracy of instruments to be used in numerous experimental investigations.

To still further aid in the dissemination of a uniform temperature scale, preparations are being made for the distribution of samples of pure metals and salts of certified melting points, thus permitting anyone to check thermometric or pyrometric apparatus in place. As a preliminary to this, a careful survey of the reproducibility of the thermal behavior of such materials from several sources of supply has been made. Among the other investigations under way or in immediate contemplation, that have a bearing on the control of thermal operations, may be mentioned studies of thermal properties of steels and refractories, including in both instances the purest obtainable materials and the commercial products; the properties of steam with respect to turbine design; the melting points of the elements and of some pure salts and alloys; gas thermometry; the temperatures of incandescent lamps; the corrections to be applied to optical and radiation pyrometers when sighting on steels, bronzes, clays, and so forth, and the comparison of the laws of radiation on which the estimation of the highest temperature is based.

Some of these experimental problems have been undertaken at the suggestion of interested individuals or corporations, who often are in a position to furnish materials that may sometimes be difficult to obtain otherwise. Indeed, the Bureau is at times in the happy but embarrassing position of being offered a great many more opportunities of this kind than it can embrace.

---

*Abstract of a paper delivered before the Congress of Technology, at Boston, April 1911.

Quarter-Centennial of the Michigan College of Mines

By Ross D. Leisk

The Michigan College of Mines, at Houghton, Michigan, will during the week beginning August 7, commemorate the twenty-fifth year of its existence by a quarter-centennial reunion. The celebration will be an affair of moment and of great interest to mining engineers the world over. Among the well known men who will be present and take part are George Otis Smith, Director of the United States Geological Survey; Chase S. Osborn, Governor of Michigan; Henry S. Drinker, president of Lehigh University; Charles Nagel, secretary of the Department of Commerce and Labor; J. Parke Channing; and George W. Perkins.

Mr. Perkins will speak on the relation of capital to labor from a mining standpoint. Mr. Drinker will take for his topic the relation of mining and mining corporations to conservation. Mr. Channing will contrast conditions at the establishment of the Michigan College of Mines with those of the present day. Mr. Osborn will talk of the relation of the State to technical education as embodied in the mining college. Mr. Smith will speak of the immediate relation of geology and the United States Geological Survey to mining.

MINING AND MECHANICAL BUILDING, MICHIGAN COLLEGE OF MINES.

The reunion will open Monday, August 7. On the afternoon of August 8, Messrs. Nagel, Osborn, and Channing will make addresses beneath an immense canopy where about 4000 people can be seated. On the evening of August 8 the alumni banquet will be held. At this banquet 800 covers will be laid. On Wednesday morning a general meeting of the alumni of the college will be held, and it is expected that a national alumni organization will be formed. There are at present a number of district associations, the Copper Country M. C. M. Club, the M. C. M. Club of Chicago, the Minnesota Association of the M. C. M., and the Southwestern Association of the M. C. M. On Wednesday afternoon Messrs. Drinker, Perkins, and Smith will speak. The evening will be devoted to class reunions and dinners to be followed by parades and illuminations.

Thursday morning and afternoon will be spent in an excursion to the mines, mills, and smelters on the north side of Portage lake. A train will leave Houghton and will carry the alumni to the mills and power plant of the Calumet & Hecla Mining Co., going from there to the Wolverine and Mohawk mills at Gay, where luncheon will be served. Returning, stops will be made at the North Ahmeek and at the Red Jacket shaft of the Calumet & Hecla. In the evening there will be class dinners and later the play, 'In Tobero,' will be presented by the college students. On Friday morning an excursion to mines, mills, and smelters on the south side will be made. The party will have a train over the Copper Range railroad and will visit the newer mines, mills, and Michigan smelter along this line. The celebration will come to a close Friday afternoon. The mine owners of the district are taking an unusual interest in the celebration, and financial and other aid has been proffered the college to insure its success.

The Michigan College of Mines was established by act of legislature in 1885, and since then has graduated [illegible] students. Its oldest building is Hubbell Hall, in which the sciences, mathematics, mineralogy, and geology are taught. The other buildings are the mechanical building, the mining building, the chemistry building, the metallurgy building, the library, and the college club house and gymnasium. The school operates a stamp mill and has its own power plant.

New York Metal Market

L. Vogelstein & Co. furnish the following report on the York metal market:

Copper.—The market is without particular feature, aside from the fact that the temporary lull in demand seemingly does not demoralize producers, as formerly, into cutting prices, and though consumers as yet are not satisfied that a conservative policy will be followed by the large producers, the undercurrent is not weak. Europe continues to buy freely. June statistics showing a decrease of 10,000,000 lb. in foreign and domestic stocks have had a good effect. In spite of large exports last month and during July to date, foreign stocks show a decrease of 1323 tons since June 30. Domestic copper deliveries, as usual, have closely followed the pig-iron output. During the first six months of this year the pig-iron output fell from 14,763,229 tons to 11,470,728 tons (22%), and copper deliveries from 173,337 tons to 150,574 tons (13%). The recent improvement in iron and steel clearly foreshadows a larger copper consumption. In fact, business in manufactured copper is undoubtedly improving, consumers admitting that they are fairly supplied with orders, and barring unexpected developments of an unfavorable character we expect this improvement to continue. While domestic consumption, as indicated by the Copper Producers' figures for June, is still unsatisfactory compared with former years, there has been a substantial increase compared with earlier months of this year. The large European shipments, together with decreasing visible stocks, show that the so-called hidden or invisible supplies abroad have been absorbed. There is every reason to believe that the average deliveries over the rest of the year will not fall below the figures of last month, and the per diem production, being already large, is not likely, at least for the next several months, to so increase as to offset the June improvement. Without deterioration of the statistical position, there is no doubt of the ability of prices to maintain themselves on the present level or even do better.

Spelter has lost some of its recent rapid advance owing to the evident unloading of speculatively held stock on the rise. Demand, however, continues good and a careful canvass of the situation seems to prove that the market is extremely sound. Stocks consist of very few parcels strongly held, while consumers are indifferently supplied and spot shipments command a premium. Producers sell forward freely against ore purchases because there is a fair margin of profit, instead of a loss as heretofore. The improvement in iron and steel, if it holds, may likewise be expected to favorably affect the spelter market.

Lead is moving satisfactorily considering the lack of enthusiasm which buyers display for it, as for all other metals, and any increase of activity will disclose absolute barrenness of stocks in the hands of producers as well as consumers. In fact, the only bar, in our opinion, to rapid advance in lead is the low price prevailing in Europe, which would permit delivery in the United States of lead exbonded warehouse, Government reports showing considerable stocks still held in bond. The market is very strong. Maintenance of present prices is seemingly assured, and a further rise by no means improbable. A review of the metal markets shows to what extent they all depend upon the general business situation. This latter is at present waiting on definite information from the West, and while the former brilliant crop prospects have suffered some impairment, the outlook is still for satisfactory harvests which will be followed by greater activity in all lines.

Tin.—Straits shipments for the first half of this month are cabled July 18 as 2375 tons and for the whole month are estimated at 4900 tons. If so, shipments for the seven months ended July 31 will have decreased 582 tons compared with the corresponding period last year. Some light as to future shipments is obtainable from figures of ore arrivals in the Straits Settlements. Owing to drought earlier in the year these arrivals January 15 to May 15 averaged only 943 tons per week, while May 15 to July 15 the average has been 1082 tons per week, or more than last year. In both 1909 and 1910 the Straits shipments were larger in the second than in the first six months, and there seems no reason to apprehend a different situation this year. On the other hand, deliveries in the United States are usually larger during the first half of the year, the excess of the first over the second six months having averaged for the past nine years, two thousand tons. To June 30, there had been a decrease of 2100 tons in U. S. deliveries and nearly 1900 tons in European deliveries, without corresponding reduction in output, with the result that whereas the total visible decreased 5218 tons in the first six months of 1910, it decreased only 589 tons in the first six months of 1911. In both Europe and America these decreased deliveries probably represent to some extent drafts on invisible supplies, though over here possibilities in that direction were limited. In Europe also the use of 'non-statistical' brands has been a contributing factor, but in this country all brands are included in statistics, and a decrease undoubtedly occurred, in harmony with pig iron and copper. While these conditions hold, tin is worth its present price only by virtue of the Syndicate. Ex-syndicate it would not sell within £50 of its present price. It should be remembered, however, that when the corner collapsed the Syndicate loaned but did not sell its tin, and is still in absolute control, and while from a statistical point of view there is nothing to warrant higher prices there is likewise nothing, so far as can be seen, to weaken this control or to bring about lower prices at present except by consent of the Syndicate.

Monel Metal

Cast monel metal has a tensile strength of 70,000 lb. per square inch, while the rolled metal is much stronger, having a tensile strength of 80,000 to 100,000 lb. per square inch. An exhaustive series of comparative tests has shown its superiority to copper and bronze under corrosive influences either in salt water, acid liquors, or under atmospheric conditions. The metal machines readily and can be forged, soldered, brazed, or electrically welded.

Monel metal contains approximately 67% nickel, 27% copper, and 6% of other metals, principally iron and manganese. In appearance it cannot be distinguished from pure nickel and takes the same finish. Its great strength, together with its extreme incorrodibility, admirably adapt it for use in marine work and engineering construction, for parts that come in contact with salt water and for valves and fittings that are subjected to superheated steam.

In general, the metallic materials of engineering may be divided into three classes: (1) irons and steels; (2) brasses and bronzes; (3) 'white metals'; or, to classify more accurately: A, alloys with an iron base; B, alloys with a copper base; C, alloys with a tin or zinc base. These three last classes are widely known and their properties under the usual conditions of service are fairly well understood.

While in the individual alloys of each series the properties of the base are modified or in some cases widely changed by the alloying material, still certain definite properties of the base remain unchanged throughout and characterize every alloy of which it is the foundation. The white metal iron gives in all irons and steels a magnetic white alloy with high strength when alloyed with carbon, a tendency to rust, and a strikingly high modulus of elasticity which remains practically constant throughout all the range from the softest wrought iron to the hardest steel. Similarly, copper makes its individuality felt throughout the brasses and bronzes. The red color may be masked and is at times entirely hidden, the hardness may vary from that of the most plastic and ductile alloys up to those which readily scratch glass, and the strength and ductility may vary greatly, but throughout they remain copper alloys, non-magnetic, with far greater resistance to corroding agencies than any iron or steel, and with the same low modulus of elasticity that marks pure copper. In like manner the so-called 'white metals', no matter how alloyed or treated, remain zinc or tin alloys; marked out from the steels and the brasses and bronzes by their fundamental constitution and its entailed properties.

In the monel metal alloys the foundation is nickel, and throughout their entire range the characteristics of that metal are impressed strongly upon all the physical properties. Nickel in its affinities and properties shows great resemblance to both iron and copper. Like iron, it forms a series of alloys with carbon, giving the complete range from those similar in carbon content to the very mildest steels up to those similar to cast iron. This carbon, while having an important bearing on the properties of the metal, does not have the overwhelming influence that carbon has on all classes of iron and steel, since nickel does not have with carbon the series of molecular rearrangements and changes in the solid which impart the varying qualities to annealed, hardened, and tempered steel. It has further a magnetic transformation point exactly similar to that of iron, being magnetic at temperatures below 325° C. and non-magnetic above that point. It has also a high modulus of elasticity, being next to iron in that respect. Its resistance to corroding agencies is well known.

All of these properties are carried to some extent into the nickel-copper alloys. The degree varies with the percentage of contained nickel, since nickel and copper in alloying form no compounds or eutectics, but simply go into solid solution in each other. In the alloys of low nickel content these properties are not very well marked, being masked by the large amount of copper present, but when the nickel exceeds 50% the alloy changes to a nickel alloy and with increasing percentages the alloys show more and more clearly the influence of that metal.

Monel metal, with its 67% nickel, shows a very successful balance between the copper alloy on one hand and pure nickel on the other; and has a remarkable likeness sometimes to steel and sometimes to bronze in its physical properties. In its tensile strength it markedly resembles steel. This is most clearly shown by the high modulus of elasticity and by the results of tensile tests. This resemblance is further noticeable in the torsion tests and in the high relation that the true elastic limit as determined with an extensometer bears to the commercial elastic limit or yield point as measured by 'drop of beam' on the testing machine.

The melting point is high (1360° C.), being nearly 300° C. above that of pure copper, and is directly dependent upon the nickel content, as is its high resistance to oxidation when hot. In its electrical properties monel metal resembles more the non-ferrous alloys; especially the 'resistance' alloys, having a high resistance and a comparatively low-temperature coefficient. Like copper and unlike steel, it cannot be welded under the hammer, but can be autogenously welded either by electricity or with an oxy-acetylene flame.

An accident recently occurred where the foreman in charge of a boiler-house opened a valve and allowed hot water and steam to blow into the ash-pit of a boiler, seriously scalding one of his helpers, who had told him a few minutes before that he was going into this pit to do some work. Six months earlier the manager talked to this foreman about carrying out a rule in regard to locking valves for the protection of men under similar conditions, and he scouted the idea that he might ever make such a mistake.

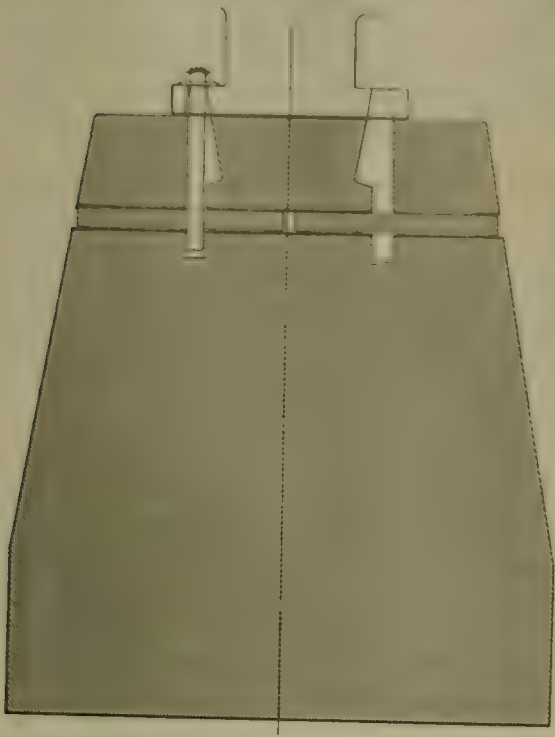
Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. The selection of any contribution is determined by its probable interest to the readers of this paper.

Battery Foundations

The Editor:

Sir—In replying to 'Puzzled Engineer', M. P. Boss shows a plan of anchorage in battery foundations which I believe is along the line of improvement over the long anchor-bolts that have been in general and universal use during the past. Other things being equal, the longer a thing is, the more weak spots it contains. However, I do not like the method Mr. Boss uses in fastening his bolts to the concrete of foundation, as much less of the strength of a given bolt is thus used, for such an uneven pull upon only one side of the head of a bolt has a tendency to rip the bolt from that side, and then the rest is easy. I here show a plan for heavy stamps. Bolts are 2½ in. by 2 ft. 4 in. long, with a slot cut in the lower end 1¼ by 3½ in., through which a key is placed, the nut is then turned up hard, which in turn pulls the key strong against the top side of a 4-in. pipe or casing. The offset is to allow for the passing of the mortar, when removing the bolt. Six instead of eight of these 2½-in. bolts should be ample. No doubt a 6-in. pipe or casing would give much more room for a man's arm, while removing broken parts. I have not tried this plan, nor have I heard of it being used, but I believe it is simple and efficient. I would be pleased to have some opinions given regarding the same.



FOUNDATION BOLTS HELD BY KEYS.

Alaskan Mining Laws

The Editor:

Sir—Complaints are made in mining journals, as well as by competent men engaged in the Government service, concerning the evils of so-called blanket location in Alaska. These evils are a great drawback to capital and private operators in developing the country. The United States mining laws have been discussed by competent and able men, and, comparing them with the mining laws of the world, I can not see where they can be improved, except in one respect.

In order to interest capital inducement enough must be given to justify the investment; in other words, ground enough should be obtainable to justify the expenditure of large sums of money for development, as men are entitled to a fair percentage to secure them for money invested. My suggestion is as follows: First, anyone who fails to do the necessary assessment work on his or their ground within the specified time shall be compelled to record the same in the District Recording Office as a forfeiture, within 30 days after the time expired; second, the Recorder shall be compelled to stamp on the face of the original the date and year thereof, under penalty if failing to do so; third, anyone who fails to comply with these rules and regulations shall be fined at least $200 and given one year in jail for attempt to defraud the United States Government out of public land.

The above additions to our mining laws, I believe, would relieve the present condition to a great extent, perhaps do away with all the evils in the near future, and give better security for capital invested, as it would show a clear record and would give no chance for a controversy to a prior locator who is not *bona fide*.

Pitch of Ore-Shoots

The Editor:

Sir—I have read with much interest the discussion concerning surface indications of ore-shoots, and would like to hear a few words on another question allied to this. I have worked for many years following rich ore-shoots, and have noticed that, as a rule, the shoots pitch to the south and west. I use the word pitch, to distinguish from the dip and strike; so, if a vein strikes north and south, and we have an orebody showing on the surface, I would look for the ore in depth on the south of the outcrop.

Several other miners and prospectors whom I have talked with have noticed this same fact, and perhaps the contributors who have already given us some valuable material will help us again on this question.

Nacozari, Mexico, July 18.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE areas of circles are to each other as the squares of their diameters. For this reason, a 6-in. pipe has a greater capacity than two pipes each of 4-in. diameter.

ANGLESITE is a natural sulphate of lead. It is an abundant ore in some localities, but cannot be said to be of wide general distribution.

TANTALUM is little used in the United States, only a small quantity being produced. A little is imported from Germany, but the use of tungsten in incandescent lamps has proved so satisfactory that the demand for tantalum will probably not be greatly increased.

ALTHOUGH the United States uses 43% of the world's output of tin, it is not an important producer of that metal. Tin is produced in Alaska and South Dakota, but not in large quantities. Several thousand tons of tin are recovered from used tin cans and other waste.

REVERBERATORY-FURNACES fired with crude petroleum, when properly handled, have about double the capacity of a similar furnace fired with wood. This makes the treatment of ore in the oil-burning furnace cheaper than where wood is the fuel.

THE first gold-mill ever sent to Japan went there in 1869 from the Vulcan foundry at San Francisco, California. It had 10 stamps and was designed for dry crushing. There were in the equipment several iron amalgamating barrels, each weighing 1175 lb. The total weight of the shipment was 35 tons.

NITRE and borax do not commonly occur together, as the nitre is much more soluble than the borax. But if solutions containing both salts were completely evaporated, the borax would deposit first, forming the bottom layer, with the nitre overlying it. The two salts may be readily separated by fractional crystallization.

NATIVE SULPHUR is of not uncommon occurrence in mines. It is the result of the decomposition of pyrite generally. Sometimes it is found in cavities previously occupied by auriferous pyrite, the gold and sulphur being together. An occurrence of this character is found in the Padre mine on Mount Gleason, in Los Angeles county, California.

NITRATES can be detected qualitatively in the field by the brown fumes given off when the substance is heated with litharge or bisulphate of potash, in a closed tube. An easy crude test is to mix the substance containing nitrates with some carbonaceous substance, such as charred filter paper, and heating, when the mixture will deflagrate. Saltpeter can be distinguished from sodium nitrate by the taste, and by the color of the flame before the blowpipe. It is also slightly more deliquescent.

WOOD ALCOHOL, acetic acid, and acetone are the chief constituents of pyroligneous acid. A small amount of tar oil, which cannot be separated mechanically, is present in the solution. In the distillation of hardwoods in the northern United States, the pyroligneous acid is manufactured into wood alcohol and acetate of lime. The process consists in heating the acid, thereby distilling over the alcohol and the acetic acid, and leaving the tar oil as a residue. This distillate, which contains the acetic acid and alcohol, is piped to another still, where lime is added. This, combining with acetic acid, forms calcium acetate, which remains in the still when the alcohol is driven off.

BOG ore deposits and similar varieties are due to circulating surface water and vegetable acids, which dissolve iron from the higher lands and deposit it again in bogs and lakes. Deposits are small in size, but are remarkable in that they are renewed after an interval of a few years. Bog ores have been mined in Quebec for several centuries. Another sub-type of limonite ores is due to the weathering in place of ores of the carbonate or pyrite type. The oxidized carbonate ores of Londonderry, Nova Scotia, are an example.

HEAD SAMPLES, whether from cars, chutes, or feeders, when taken by hand, constituting what are known as 'grab' samples, afford only an approximate idea of the value of the ore coming to the mill. Where no amalgamation is practised in the mortar, perfectly reliable samples may be taken as the sand issues from the battery, by the employment of properly designed automatic sampling machinery, using one which takes all of the stream at regular intervals, in preference to one that takes a portion only of the stream all of the time.

DECAY of wood is due to the growth of microscopic fungi which flourish under proper conditions of heat, moisture, and air. When completely excluded from the air, as when submerged in water, wood will remain sound for long periods without requiring preservative treatment. Wood is composed of fibre and cellular tissue. The fibre is quite durable and, by itself alone, resists attack on decay germs, but the cellular tissue, composed largely of albuminous substances, which act as soil and sustenance for the growth of decay organisms, soon breaks down, involving the destruction of the whole substance of the wood.

PYROLUSITE is a soft black mineral, of the composition MnO_2, and can be easily distinguished from other manganese minerals by its softness and black streak. It represents the final stage in the alteration of manganese minerals. The larger part of that mined in this country comes from Virginia, Georgia, and Arkansas, although deposits exist in many other States. Pyrolusite is used in the manufacture of chlorine and oxygen, and in the preparation of spiegeleisen. It is also used in coloring and decoloring glass, and as an oxidizing agent in varnish and paint. The crude ore is quoted at $10 to $25 per ton in San Francisco.

THE enlarged-homestead law permits the entry by one person of 320 acres of Government land in the arid States which is not, in the understanding of the Government, susceptible of irrigation. As under the 160-acre homestead law, this land can be acquired by the settler from the Government free of cost, on compliance with the regulations requiring residence and cultivation. The determination of what lands are subject to these double-sized homesteads devolves upon the Secretary of the Interior, and since the passage of the act in February 1909, 190,254,495 acres have been designated by him as subject to entry in units of 320 acres. Every month additional lands are thus designated, 90,242 acres having been added to the total in June.

TO obtain the flow of the stream in second-feet roughly, select some portion that is as straight and uniform as possible, for, say, 300 ft., and then measure the width and depth at six or eight places, from which may be obtained an average width and depth. This multiplied together will give the average cross-section in square feet. Next drop a float on the water, noting the number of seconds it takes to travel the given distance. From this can be calculated the velocity of the water in feet per second. Multiply this by the average cross-section in square feet and the product will be the cubic feet per second of flow. As the surface velocity is somewhat greater than the average velocity, the result should be reduced one-fifth. For larger water-powers, more accurate methods, using the weir or current meter, should be resorted to.

Special Correspondence

JOHANNESBURG, TRANSVAAL

Monthly Gold Output Nearing £3,000,000.—Summary of Production.—[illegible].—At[illegible] Railway [illegible].—May [illegible].

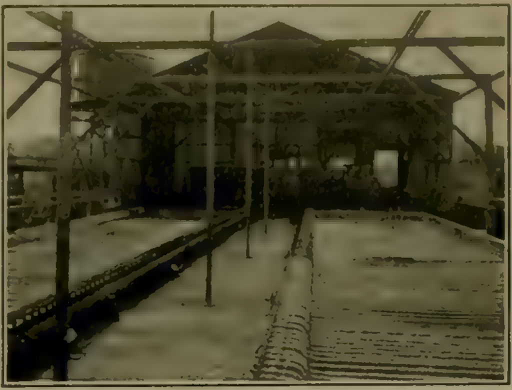
There is every indication that the gold output of the Transvaal will soon exceed £3,000,000 per month, and unless something untoward happens, this position should be attained in the month of July. May was another record month, the total mineral output, according to the official mining statistics, being as follows: gold, £2,920,806; coal, £89,950; tin, £48,738; lime, £9614; silver, £8072; flint for tube-mills, £750; miscellaneous minerals, £100; total, £3,078,230. The value of the output of diamonds is not declared monthly in the official returns, owing to the Premier mine being the only working mine of any importance in the Transvaal, all the other diamond mines being merely prospecting ventures. The following summary of the sources of the Transvaal gold production will show how little of the precious metal is produced outside the fields of the Rand:

	Ounces.	Value.
Witwatersrand, including Heidelberg and Klerksdorp	667,664.341	£2,836,056
Ottoshoop	86.420	367
Pretoria	38.286	163
Barberton	8,251.748	35,052
Lydenburg	11,406.240	48,450
Pietersburg	168.922	718
Totals	687,615.957	£2,920,806

With the starting of the new mill at Brakpan, the reappearance of the Meyer & Charlton, growing outputs from Randfontein, and return to normal rate of production at the East Rand Proprietary mines, there should be no difficulty in producing a £3,000,000 output for the month of July.

Mention has already been made of the unsatisfactory outlook for the Transvaal coal industry, on account of the continued steady decline in pit-top selling prices, and if this continues the Transvaal will soon be competing for the questionable honor of ranking with Japan and India as being one of the cheapest coal countries in the world. For a long time the selling price remained in the neighborhood of 5s. per ton at the pit-tops, but about a year ago a downward tendency set in. Prices continued to decline until for the month of May the average selling price was 4s. 8.21d. per ton. The average pit-top selling price seems to have resolved itself into one of railway position with regard to the Rand, the question of quality being of little or no importance. For instance, the Springs coal, owing to its close proximity to the Rand, commands 5s. 9d. per ton for coal running up to 30 or 40% of ash content, while Middelburg coal with less than half that percentage of ash, realizes only 4s. 6d. per ton. In the outside districts farther from the Rand, the average pit-top selling price is only 4s. 5d. per ton. This low selling price is caused by the Consolidated Gold Fields of South Africa having gone to Breyton in the Ermelo district for its coal supplies, where the railway rate is about a shilling per ton higher to the Rand than that from Middelburg district. This higher railway rate naturally affects adversely the pit-top price. Formerly the rate was two shillings higher, but by agreement between the railway and the Consolidated Gold Fields, a shilling reduction in the railway carriage has been made, much to the chagrin of the local Coalowners' Association and the companies owning collieries in the Middelburg district. Protest meetings are being held in the Middelburg district, and the lower railway rate allowed for carriage of coal from more distant fields is being denounced as preferential and unfair to those who have sunk capital in establishing collieries in the Middelburg district on the basis of the old railway rates. The question for some time has been hotly discussed, and may lead to friction [illegible] and perhaps a quarrel between the Coalowners' Association on the one hand, and the South African Railways and the Consolidated Gold Fields of South Africa on the other.

The most prominent feature connected with the returns of the base mineral output of the Transvaal in May was that of tin ore, which was again a record value of £48,738 out of a total base mineral output value for the month of £[illegible]. No copper ore was shipped during May, nor, for the matter of that, was there any zinc produced. Magnesite from the Malelane deposit ceased to figure in the list after a regular appearance for some time. It seems not at all unlikely that tin may soon displace coal and become the second most important mineral production of the Transvaal. Very good accounts still come to hand from northern tinfields; two large and promising mines have established themselves as dividend payers, and with proper and careful management other properties are likely to follow in their footsteps. The tin industry of the Transvaal has a short but checkered history extending only over a period of eight years. When first discovered in the Bush, the tin prospect caused considerable excitement, as the prospects were alluring, but experts who should have known better, added materially to the excitement by their unjustifiable and optimistic reports. The district was never more than a prospect, and it remains one still, although one German expert compared the district to the Rand goldfields, much to the disadvantage of the latter. These experts have learned better since then, and so have those who speculated on their advice and lost, with the result that the more recently discovered Waterburg tinfields have been and still are regarded with suspicion by speculators. The first discoveries spoken of petered out in depth, and that district became discredited. Some of the discoveries in the Waterburg district, too, have not turned out well, but others have far exceeded expectations, and, speaking generally, this field promises sooner or later to make up for all the disappointment suffered in the Bushveldt tinfields.



FILTER-PLANT, CROWN MINES.

One peculiar feature about the increased outputs of gold almost every month is that the profits do not seem in the aggregate to increase in the same proportion, and the only inference to be drawn from this is that either the grade must be declining or the costs of working increasing, or perhaps both may be occurring. This, however, seems to have been happening for the past six half-years. The tonnage milled has been steadily increasing. It has increased by at least 200,000 tons during the last year, but the value obtained, although it has increased, has only done so to about 50% of what it should have done had the value been maintained. As far as can be seen at present, the profits in the aggregate during the current six months will again show a decline. At all events, the profit-earning capacities of the mines must not be judged by the gross output. F. H. Hatch has recently estimated that the deposits can be worked to a depth of 6000 ft., corresponding to a life of 35 years.

AUSTRALASIA

STATE COLLIERIES.—PAPUAN COAL.—AUSTRALIAN AND AMERICAN COPPER PRODUCTION.—AUSTRALIAN GOLD MINERS' WAGES.

The system of State collieries—which forms one of the planks of the platform of the Labor party in Australia and New Zealand, as being a step toward the nationalization of the industry -is by no means an unqualified success, the miners' unions refusing, as a rule, to permit the work to be conducted on a commercial basis. In New Zealand it is asserted that the State collieries do not pay their way, and that considerable quantities of New South Wales coal have to be used. In 1910 the output was 281,630 tons, being a decrease of 5321 tons compared to the previous year. In Victoria the State mine at Powlett river has materially affected privately owned collieries, by reason of the higher wages offered and lighter conditions of labor, but the quality of the coal obtained is stated by the New South Wales Under-Secretary for Mines to be inferior. It is the same with the coal from the State mines at Collie, Western Australia. The New South Wales Government has introduced a bill into the State Parliament for the establishment of three State-owned collieries, although the output in the northern district has been considerably decreased and large numbers of miners are unemployed.

There is reason for believing that the reports of payable coal seams in Papua are well founded. An expedition sent out by the Papuan Development Syndicate of Sydney to explore the country in which indications of coal were found a couple of years ago, has found three seams of excellent quality, one 12 ft. thick, and two 3 ft. thick each. The coal is easily got at, but the country is difficult of access. The syndicate has obtained a reward concession of two miles, which is reached by cutting a track through the dense tropical vegetation a distance of twenty miles from the Kikori river.

Although copper is one of the most plentiful of minerals in Australia, the cost of production in some places is considerably in excess of what it is in America, thus placing it at a disadvantage in the market. For instance, in South Australia it cost the Wallaroo & Moonta M. & S. Co. in 1910 £54 11s. 2d. per ton to produce refined copper by mining and cementation and to place f. o. b. ocean steamer, as against £53 3s. 11d. in 1909. The average selling price in 1910 was £58 7s.; consequently the profit per ton of copper produced was only £3 8s. 10d. per ton. This does not compare favorably with the figures supplied by some of the American mines, the Anaconda, for instance, where the cost of production, including all charges, is from £39 13s. 4d. to £42 per ton. The largest production is in Queensland and Tasmania, which furnished in 1909 copper and ore worth £1,461,234, against £878,754 from the other States.

A demand for higher wages and improved conditions of labor is being made by a number of gold miners employed on the Ballarat, Bendigo, and other Victorian fields. The increase represents an advance of something like £1,000,000 per annum on the cost of gold production in the Commonwealth, forming a heavy handicap on industry. The reason advanced is the increased cost of living, a natural result of the artificial raising of the rates of wages in almost every branch of productive and distributive industry by the Australian trades unions, which are seeking to secure uniform rates of wage and conditions of labor throughout the Commonwealth. The effect on Victorian gold mining alone, should the demand be persisted in, will be most serious. In 1908 the calls actually paid amounted to £395,887, while the dividends totaled only £319,293, leaving an actual loss of £76,594, without taking into account the interest on the capital invested or depreciation. In 1909 the amount paid in dividends showed a decrease, and there was no improvement in 1910. There are about 50,000 gold miners employed in the Commonwealth, and should the cost of production be increased, the closing of mines which barely pay their way, or are worked at a loss, will become necessary.

ELY, NEVADA

DEEPENING GIROUX SHAFT.—CHARACTER OF ORE.—WORKING LOW-GRADE ORE AT NEVADA CON.—REOPENING THE VETERAN.—RUTH MINES.—PROGRESS AT BLACKHORSE.

The management of the Giroux Consolidated has stated that it will sink the Giroux shaft from the 1400 to the 1800-ft. level. The shaft, which has five compartments and is said to be the largest in the State, is being sunk in solid limestone. Cross-cuts have been driven from the 700, 1000, 1200, and 1400-ft. levels to the Alpha orebodies, which are being extensively developed. The continuation of the big shaft from the 1400 to the 1800-ft. level is an indication that the management is satisfied with the ore above. Only two compartments of the shaft will be sunk to the 1800-ft. level, after which a station will be cut and the other three compartments raised to the 1400-ft. level. The management now is experiencing difficulty with soft ground and water in the cross-cut on the 1400-ft. level, which is making 650 gal. of water per minute, the full capacity of the pump on that level of the mine. Development of two orebodies on the 1200-ft. level is being pushed rapidly. The ore carries native copper and oxide, and is of sufficient grade to stand shipping to the smelters of Utah, where it will be treated until the company decides upon the erection of a plant of its own.

The Nevada Consolidated is now producing about 11,000 tons of ore per day, all of which comes from the Copper Flat pit, and is handled by steam-shovels. For some weeks the company has been mining and treating very low-grade ore, said to average less than 1% copper, from which it is able to make a profitable extraction. This would not be possible were it not for the fact that all other ore and waste had been removed. To carry on further development it was necessary to remove this low-grade ore, and as an experiment, a test run of the ore was made through one section of the concentrator at McGill, twenty-one miles distant. At present two sections of the plant are running on the ore, which is returning a good profit. The company is also mining a large tonnage of oxide ore averaging from 3 to 5%. This ore is crushed at the concentrator and stored away for future use. It is too low grade to treat with the present equipment, but it is probable that the company will erect a leaching plant, when this class of ore will be found very profitable. Both in Spain and Japan copper ores have been treated by leaching processes at a profit, and some similar process will probably be adopted here.

It is expected that the company soon will resume operations in the Veteran mine, which has been shut down on account of labor troubles for the past two years. In this property the caving system was inaugurated, and was working successfully when trouble arose with the miners over the contract system. The ore averages between 3 and 4%, and carries considerable iron, which is of advantage in smelting the product of the Nevada Consolidated mines, which carry a considerable amount of silica. It is expected that the Ruth mines of the Nevada Consolidated, which are extensively developed, will be opened for production during the present year. The Ruth property has 13,000,000 tons of ore developed, which will be mined by the caving system and hoisted to the surface through the Star Pointer shaft, which has not been used since its completion more than three years ago. The company is by no means short of ore for its steam-shovels, but will resort to deep mining, especially during the winter months, when much difficulty is experienced with frozen ore from its surface deposits.

Considerable mining is now going on in the eastern portion of White Pine county, especially at Blackhorse, where the Amalgamated Nevada Co. is operating extensively. The company recently started two shafts for deep development work, to test its ground. Its 10-stamp mill at San Pedro is running on part time, and is said to be making a close saving. The company has expended more than $200,000 during the past two years in the purchase of property, equipment, and development.

LONDON

Activity in Old Cornish Shafts.—Radium Production at St. Ives.—Electric Plant at Giew Tin Mine.—Murex Process at Broken Hill.

As I have often stated in these columns, the mistake made by Messrs. Schiff and Dietzsch in connection with their various Cornish ventures is that they erect expensive surface plants before knowing what ore is available in the old properties they take up. They started work eleven years ago at the Hingston & Clitters mines in East Cornwall, and they have since then reopened groups of abandoned mines near Truro, and near St. Ives, and have also acquired the West Kitty and other properties in the neighborhood of St. Agnes. Though large sums have been spent, no profit has yet been earned. The venture at St. Ives has been rendered attractive by the radium boom. The company, St. Ives Consolidated Mines, was formed just three years ago, and work has been centred on the Trenwith mine, which yields pitchblende, and on the Giew tin mine. The Trenwith has been unwatered, and a subsidiary company, the British Radium Corporation, is extracting uranium and radium compounds at the laboratory at Limehouse, London, under the scientific direction of Sir William Ramsay. Up to the time of writing, £10,098 has been received from the sale of radium and uranium compounds, while orders valued at £4300 are in course of execution. The directors do not say how much of the products are radium and uranium compounds respectively. At the Giew tin mine unwatering was at first undertaken with a Cornish pump, but subsequently an electrical installation was provided. The electric generating station contains Diesel oil engines. Twenty stamps and a concentrating plant have been erected and they started work at the beginning of 1911, chiefly on dump material. Up to June 19 the amount of tin concentrate sold to the smelters was 25 tons.

Additional leases have been acquired, including the Trink Hill, and an old dump. The latter is estimated to contain sufficient tin to warrant the erection of another 20 stamps. At the Giew mine the water-level has been lowered to 480 ft. below adit, or about half the depth of the former workings. A vast amount of work has been done in clearing old adits and shafts and putting them in order, and the report of Ferdinand Dietzsch, the engineer, gives details on this point. It is not possible, however, to obtain from the report any idea of the ore reserves or of the prospects of the mines as producers of profitable ore.

It is announced that a radium spa at St. Ives is about to be started. The capital of the company is £220,000, of which £80,000 is in cumulative 6% preference shares and £140,000 is in ordinary shares, the latter being the purchase price paid to the parent company, the National Minerals Corporation, for the leases. The expenditure during the period from October 1, 1909, to December 31, 1910, was £70,850, of which £44,954 was on plant, machinery, buildings, and surface works, and £13,555 on development. There is a liability of £23,850 for money advanced by the National Minerals Corporation. Presumably the finances will have to be rearranged shortly, as the probability is that further working capital will be required.

Two years ago there was a tremendous boom in the shares of the Murex Magnetic Co., which was formed by people identified with the Shell Oil Co., for the purpose of working A. A. Lockwood's invention for magnetically concentrating non-magnetic sulphides. The principle on which the process was based consists of the addition of a small proportion of magnetic substance such as magnetite or sulphide rendered magnetic by a roast, and agglomerating the particles by means of some organic substance such as oil in emulsion of water, the agglomerated particles then being removed by passing the pulp under magnets. The boom was a perfectly ridiculous performance, quite unwarranted by any practical results thus far obtained, but recognizing that the process had a scientific substratum, *The Mining Magazine* published a detailed description of what the inventor and promoters claimed. Fairly good results have been obtained at the Cordoba Copper Co. in Spain. But the venture at Broken Hill was the great sheet anchor, and the results of the trial plant erected there were eagerly awaited. It is a disappointment therefore to find that the plant has failed. The plant was being tried on Block 14 ore, of which there is a large reserve of too low a grade to treat by the usual methods. Altogether, 1521 tons of sulphide ore was mined for the purpose of testing the process, averaging 12%, lead, 8¾%, zinc, and 9¼ oz. silver. In the last continuous run of the plant, 661 tons of ore was treated assaying 12%, lead, 8¼%, zinc, and 8⅔ oz. silver, and 185.6 tons of concentrate was produced, assaying 31%, lead, 21%, zinc, and 19⅔ oz. silver, being an extraction of about 72% of the lead and zinc and 61% of the silver. The other part of the Murex process, namely, the separation of the two sulphides by means of silicate of soda, has not been a success so far, but experiments are still being made. The engineer of the Block 14, H. Voss Smith, has therefore abandoned the plant, and other steps are being taken for the beneficiation of the large amount of sulphides still in the mine. George Weir, the manager of the North Broken Hill, has been asked to examine the mine and the mill and make suggestions as to the best course to pursue. The Murex company has many contracts in other parts of the world and the measure of success attending them has not yet been announced.

SILVERTON, COLORADO

Bagley Adit Work.—Vermillion Ships Ore.—Hydro-Electric Plant at Sunnyside Mine.—Pride of West Closed.— Revive Mine Owners' Association.

The Frisco Tunnel Co., operating the Bagley adit at Animas Forks, has connected with the old Red Cloud shaft through a three-compartment raise. The property is closed temporarily, pending an examination of the orebodies exposed and the completion of arrangements for milling. The Bagley adit is over 11,000 ft. long and has cut several veins in addition to the Red Cloud. These carry valuable gold, silver, lead, zinc, copper, and iron ore. The Vermillion is operating steadily, milling 75 tons per day and shipping a large amount of crude ore from a recent discovery on the Equator claim. The company employs 75 men. The ore and concentrate are hauled by wagon one and one-half miles to Animas Forks, the nearest railroad point. The Sunnyside mine is operating its new hydro-electric plant, situated at Midway. The plant consists of one Pelton water-wheel and two generators with a total capacity of 600 kw. The plant has been supplying 300 hp., but this has now been increased to 400 by enlarging the transformer capacity. The current was formerly carried from the plant to the mine, about three miles, at a voltage of 2300. At present the voltage used is 10,000. The mill is running steadily and dropping 40 stamps, the full capacity.

The Gold King, at Gladstone, is running at half capacity, but the concentrate is poor and the life of the leasing company probably will be short. The mine needs considerable development, and can hardly be expected to pay until this work is done. The Silver Lake is pushing development and employs 18 men. The mill was to have started on July 10, but is still idle. It is rumored that it will be operated after August 1 and will mill 50 tons per day. The Iowa Tiger Leasing Co. has failed to discover the suspected orebody, but development is being pushed vigorously and the lessees are confident that new ore will be found. The average grade of concentrate has fallen from $40 to $35 per ton, net smelter returns, within the past two months. This is due to a decline in the percentage of lead from 40 to 30. The mill is grinding 100 tons of ore per day, but produces only 12 tons of concentrate. The King mine is being developed by the King United M. Co., but no report of progress is available. The owners of the Hercules are in Silverton to perfect plans for the future operation of this mine. The Bandora mine, on South Mineral Creek, is being examined by Richard

Parker, of Denver. At this mine recently a vein of rich silver ore was discovered, but the extent of this is not known. The Ledge mill started July 23, and, when the new machinery is adjusted, is expected to handle 200 tons per day. This will give 50 tons of concentrate, in the proportion of 15 tons 50% lead to 35 tons 40% zinc, both carrying about $2 gold and $5 silver per ton. This mine, under the present lessees, has had a checkered career, marked by mismanagement and interference with the local managers on the part of stockholders. It is now managed by W. Z. Kinney, manager of the Gold King mine in its best days, and he is expected to put the mine in its right position as one of the San Juan's best producers. The mine has a large tonnage of lead-zinc ore blocked out and the problem at present seems to be entirely a milling one. The mill operated during the summer and fall of 1910, but saved only a fraction more than 50% of the assay value of the heads. The new machinery is relied upon to increase this saving to a minimum of 75%, but the result is doubtful, as the installation is entirely experimental and includes jigs, which were tried and failed to give satisfaction under previous managements. It is only just to Mr. Kinney to state that he is in no way responsible for the new equipment, as he only recently assumed the management and the plant was turned over to him as it is operating at present.

The negotiations for the sale of the Congress have failed and the owners have leased the dump and all the old workings above the 72-ft. level to local people and work started July 24, with a force of two men for the present. The Pride of the West has closed after shipping several cars of lead ore. The company's affairs are reported as badly tangled, and inside friction seems to have been the real cause of the shut-down. A delegation from the Denver Chamber of Commerce visited Silverton July 12 as the guests of the Commercial Club. The visitors inspected a number of the large mines and returned to Denver, where they will report to the Chamber of Commerce on the mining resources of this district and offer suggestions for the improvement of local conditions. The Mine Owners Association has been revived and most of the principal operators of the district have joined. This association was formed during the labor troubles in Colorado to handle questions arising at that time, but as there is no trouble of any kind now and no reason to suspect any in the near future, the association will devote its time to matters of general interest and endeavor to better existing conditions in regard to milling, shipping, and smelting. These matters will be carefully studied in an effort to raise the percentage of saving in the mills, and to secure equitable freight and treatment rates.

NEW YORK

Dullness of Markets.—Possible Change of Ownership of Ohio Copper.—Chino.—Copper Situation.—Consolidated Gold Fields Activities.—Pioche Complexities.—Spelter Statistics.

There is but one fruitful topic of discussion in Eastern financial markets during this remarkable season, the prevailing dullness, the reason therefor, the Federal prosecutions, past, present, and future, all tending to one everlasting always persistent query: when is the turn in affairs to come? It does not need to be added that market operations are meaningless. For the past month a certain volume of trading has been maintained in order that the utter lack of public support might not be so obvious. Mining markets are deserted. The holders of copper shares seem to have withdrawn entirely from all operations. The larger copper producers claim to be enforcing some degree of curtailment, but there is no great hope of an improved report covering July output. Consumers are not stocking up and the export demand is not making any such record-breaking showing as it did in June.

Further details as to the possible acquirement of Ohio Copper by the Guggenheim interests are being made public. It is said that an offer of 80 has been made for two-thirds of the unplaced bonds, provided the Catrow interests will agree to take the rest of the bonds, and provided further that 100% stock bonus goes with the bonds. The offer would seem a fair one in view of a sale at auction recently when a large block of Ohio bonds sold under 30. When the market is in the doldrums no prophecy can be made as to the effect of news, either good or otherwise. In June, the Greene-Cananea made a low record cost of 9c., and the market slumped steadily, losing more than a point without any reaction. While the talk of curtailment is heard as ground for hope of a better metal market, there is also to be noted the progress made by the properties just coming into production. Chino is apparently to make good a reasonable part of the extravagant things Lawson said about it some years ago. The power-plant is to be turned on within the next four weeks, and the first ore will go through the mill before the end of August. It is anticipated now that Chino will be producing on a basis of 55,000,000 lb. annually on January 1. The Chino ore reserve is now estimated at 51,500,000 tons averaging a little better than 2.28% copper, and there is a large territory yet to be explored. Seven drills are in operation, and additional ore is being steadily developed.

When the copper situation is analyzed the complete control of the low-grade milling properties is so apparent that there seems to be no other factor worthy of lengthy consideration. It is safe to say that during the next few years the deep-level mines must be governed almost wholly by the action of the porphyries. For the time being merger talk has been dropped entirely, and until a great change in the politico-legal aspect of business affairs occurs, is not likely to be revived. L. D. Ricketts of the Greene-Cananea Copper Co. is to have charge of the reconstruction of the plant of the Arizona Copper Co. The committee of directors visiting the property have reported favorably upon a new smelter site, and the installation of reverberatory furnaces. The work will involve the expenditure of some $1,500,000, which will be supplied by the sale of debentures in Scotland.

There has been some forced liquidation in the Canadian mining issues, both in Cobalt and in Porcupine stocks. The decline in Nipissing brought out a rumor of a cut in the dividend. A cabled inquiry sent to George H. Earle, now in Europe, brought a specific denial of any such intended action. There have been many cases of financial distress since the Porcupine fire, and it is not to be wondered at that the market has been under pressure. The action of Hollinger has shown manipulation a little too plainly, and the public has not taken it as well as was hoped, nor has any degree of market cohesion been established. The position of the Consolidated Gold Fields of South Africa in regard to the Rea mines is still doubtful, though a semi-official announcement has been made to the effect that the company is entirely out of Porcupine. It is now said that this company is to organize a subsidiary with $8,000,000 capital for work on this side of the water, and that some large interests in the Yukon country have been taken over on the advice of John Hays Hammond.

As repeated announcements of the completion of the Nevada-Utah-Amalgamated Pioche merger have been made, it has become a fixed custom to follow up each one with a denial. Now, the announcement is made final that deeds and stocks have been exchanged and the Nevada Utah now controls every important mine in the district, except the Prince Consolidated. The much involved, doubled, and twisted organization of the Nevada-Utah is now to be further complicated by the creation of the Amalgamated Pioche Mines Corporation which will hold the physical title to all the properties, and which will in turn be controlled by the Nevada-Utah through stock ownership.

Statistics compiled by the U. S. Geological Survey show that the production of spelter for the first six months of 1911 was 140,196 short tons, a gain of more than 5000 tons over half the record output of 1910. Of this 5135 tons was made from foreign ore. Spelter stocks were reduced from 23,232 tons to 17,788 tons. Imports remained the same, but exports were nearly double those of half the preceding year. The apparent consumption of spelter was 135,497 tons.

General Mining News

ALASKA

Petitions for the establishment of an Alaska coal mining commission to operate public coal lands in the territory have been circulated in Seattle, Washington. The petitions are to be sent to President Taft and Congress. It is asked that the commission have authority to build railroads from the mines to Controller bay, build docks, bunkers, and accommodations for ships, maintain colliers, and establish Government bunkers at Seattle, Tacoma, and other Puget Sound points from which to sell coal direct to the people.

Treadwell District

The Alaska Treadwell Gold M. Co. for the month ended July 26 has issued the following report: Mill time, 31 days. Full mill of 240 stamps ran 29 days, 22 hr., 45 min.; water power, 27 days, 8 hr., 27 min.; steam power, 2 days, 14 hr., 18 min. 300-stamp mill, water power, 30 days, 16 hr., 45 min. Ore crushed, 84,840 tons, as follows: 240 mill, 33,460 tons; 300 mill, 51,380 tons. Sulphides saved, 1568 tons, as follows: 240 mill, 610 tons; 300 mill, 958 tons. Estimated gross value of free gold, $99,579.23; estimated gross value of sulphides, $84,653.77; estimated total production, $184,233; estimated total realizable value, $179,035.54.

Operating expenses, $92,232.30; net operating profit, $86,803.24; construction expenses, etc., $17,688.51; yield per ton of ore milled, $2.17; stock of broken ore increased 906 tons. Development work, 618 ft., as follows: 1450-ft. level, 40 ft. in ore, average assay value, $4.06; 1600-ft. level, 541 ft. in ore, average assay value $5.76; 37 ft. in waste.

The Alaska Mexican G. M. Co. for the month ended July 26, has issued the following report: Mill time, 31 days. Full mill of 120 stamps ran 30 days, 16 hr., 52 min.; water-power, 30 days, 16 hr., 52 min. Ore crushed, 18,694 tons. Sulphides saved, 450 tons. Estimated gross value of free gold, $22,113.68; estimated gross value of sulphides, $26,283.35; total, $48,397.03; less value 479 tons United ore, $1304.08; total production, $47,092.95; total realizable value, $46,622.02. Operating expenses, $27,235.13; net operating profit, $19,386.89; construction expenses, etc., $3495.93. Yield per ton of ore milled, $2.52; stock of broken ore increased 4030 tons. Development work, 136 ft., as follows: 1210-ft. level, 5 ft. in waste; 1320-ft. level, 27 ft. in ore, assay value 43c., 58 ft. in waste; 1570-ft. level, 25 ft. in waste; shaft, 21 ft. in waste.

For the same month the Alaska United G. M. Co. has the following report: Mill time, 31 days. Ready Bullion mill (120 stamps) ran 30 days, 3 hr., 1 min.; water-power, 26 days, 3 hr., 42 min.; steam-power, 3 days, 23 hr., 19 min. 700 Ft. Claim mill (100 stamps), ran 30 days, 14 hr., 35 min.; water-power, 16 days, 9 hr., 39½ min.; steam-power, 14 days, 4 hr., 55½ minutes.

	R. B. Claim.	700 Ft. Claim.
Ore crushed, tons	18,902	15,603
Sulphides saved, tons	462	285
Estimated gross value of free gold	$20,868.50	$18,448.30
Sulphides	20,117.07	13,764.84
Total production	$40,985.57	$32,213.14
Total realizable value	40,575.72	31,904.05
Operating expenses	$28,797.92	$23,962.50
Net operating profit	11,777.80	7,941.55
Construction expenses, etc	2,280.11	6,701.67
Yield per ton milled	2.16	2.06

Development work: Ready Bullion Claim, 387 ft.; 1350-ft. level, 167 ft. in waste; 1800-ft. level, 112 ft. in ore, assay value, $2.81; 1100-ft. level, 108 ft. in waste. 700 Ft. Claim, 654 ft.; 1210-ft. level, 342 ft. in ore, assay value $2.32, 18 ft. in waste; 1320-ft. level, 182 ft. in ore, assay value $3.62; 1600-ft. level, 112 ft. in waste. Stock of broken ore: R. B. Claim, 1871 tons; 700 Ft. Claim, 7040 tons.

Ketchikan

The Mt. Andrew mine is delivering 100 tons of ore over the aerial tramway to the bunkers on the beach daily. The steamship *Meteor* loaded 2000 tons of ore at Sulzer from the Jumbo mine on July 5 for the Ladysmith, B. C., smelter. The remainder of the ship's cargo consisted of 1000 tons of marble from Tokeen inlet and consigned to the factory at Tacoma. Several new discoveries have been reported from the head of Portland canal, the ore in that part of the district is principally lead, silver, and gold.

Valdez

An orebody has been discovered at the Ibex mine near the glacier, it is reported, which it is believed will average $40 per ton. Some of the ore assayed as high as $340 per ton. The vein at a depth of 60 ft. was 3 ft. wide, and apparently was widening.

Yukon

The Yukon Gold company is delivering material on claim No. 7 for the first dredge on Eldorado creek. Ground broken by the early prospectors, 15 years ago, will be worked over by the dredge. Another dredge will work on No. 6 claim, above Bonanza.

ARIZONA

Mohave County

The transfer of the Gold Road property to the United States S. R. & M. Co. is said to be the largest mining deal in the history of Arizona. The purchase price was $1,600,000, of which $1,200,000 was delivered to the owners and $400,000 to the bondholders of the Gold Road company. The price originally asked was $2,000,000.

CALIFORNIA

Inyo County

The official report of the Skidoo M. Co. for June is as follows: Amount company ore milled, 1331 tons; amount of lessees' ore milled, 142 tons. Time lost, 5½ days. Value of bullion produced, $14,696.19; value of cyanide produced, $4153.68; royalties and custom milling, $888.55; total receipts, $19,738.42. Cost of development, $667.93; cost of operation, $7673; total, $8340.93. Net profits for month, $11,397.49.

Kern County

A Cuplin pneumatic gold separator is being constructed at the old Goler dry-washing fields, nine miles west of Randsburg, by a Chicago syndicate, state press reports. R. W. Fairfoull is at Randsburg for the syndicate. The machine will be one of the largest portable dry-washing plants ever built. In the early days hundreds of men found employment at the fields, where they used the small hand dry-washing machines. Some made small fortunes, but the diggings afterward were practically abandoned.

Nevada County

(Special Correspondence.)—The North Star Mines Co. has placed an order for a large electric pump, to be installed in the Providence shaft of the Champion group. The Providence mine has been one of the most prolific and profitable producers of the group now comprising the Champion holdings. The working force has been increased, 60 men now being on the payroll. Driving from the 1000-ft. level of the Champion shaft will commence shortly, according to reports. Arrangements have been practically concluded for the taking over of the California mine, about four miles from Grass Valley, by the Scribner-Onn Gold Mining Co. The California has been developed to some extent and shows ore of fair grade. The Scribner-Onn interests control the West Point, Dolly Madison, and Alta mines, in the Rough and Ready district, and are said to be planning to take over other groups. San Francisco capital is largely interested. The management expects to have the new plant at the Union Hill mine in commission early in the fall. The renewed reports that the California Midland Railway Co. plans the early building of its line from Marysville to Grass Valley has reawakened interest in the copper properties in the Spenceville district. The

Iron Mountain mine, considered the best property in the section, is controlled by the U. S. Smelting, Refining & Mining Co. Otto Wascott and associates are developing a nearby group and expect the presence of excellent grade ore. The Midland is expected to traverse the district, as the surveyed route passes through the Spenceville road.

Nevada City, July 29.

PLACER COUNTY

George Hetersall, F. S. Morgan, C. B. Brown, H. Brown, J. Botte, and A. Nicholls have bonded the Heath placer mine, one mile from the Lost Emigrant mine. The ore will be stamped at the Lost Emigrant mill.

TUOLUMNE COUNTY

(Special Correspondence.)—The Black Oak is employing a crew of about 40 men. Shipments of the richer ore are being made regularly to the Selby smelter, the balance being milled at the property. The outlook is said to be more promising than at any time in the past.

The Starr King mine, near Tuolumne, shut down a few years ago after the destruction of the mill by fire, has been unwatered for inspection by prospective purchasers. It is said rich ore was uncovered on the bottom level, 800 ft. deep, just before the burning of the mill.

The New Albany, owned by the United Mines Corporation, is being operated with renewed activity. It is said that 600 tons of ore recently milled averaged better than $25 per ton. Extensive repairs are being made to the mill, during the progress of which work only one-half of the stamps are in operation.

Preparations are under way for the resumption of development operations at the Crystalline mine, near Jamestown, owned by C. F. Stater. It is reported that the Gold Wing mine, four miles south of Tuolumne, is to be reopened.

The Mansfield gravel mine, on Yankee hill, acquired recently by T. C. Crawford, is soon to be operated again. Gravel containing gold has been found on the Davies ranch, near Columbia. A three-compartment shaft will be sunk. A Keystone drill was used in prospecting. Forty men are employed at the Dutch mine and the 20-stamp mill is in continuous operation on ore of good grade. The Phoenix Lake M. Co. will erect a mill on its property near Confidence in the near future.

The Center Ledge M. Co. has taken a bond on the New York Tunnel mine, on Table mountain, near Rawhide, agreeing to pay $4000 for the property. During the life of the option the company must extend $300 each month in development and pay 20% of the gross output of the mine to the owners, J. R. and T. M. Bevan. A crew of 8 men is employed at the Gem mine, near Confidence, operated by J. N. Wagner and others, and prospects are reported as being good. A long pipeline has been laid. The Alta Vista Co., of Los Angeles, has acquired by bond the Fair Oaks mine, near Confidence.

Tuolumne, July 30.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Georgetown is to have a [illegible] concentrating plant. It is thought the town board will act favorably on a request by J. J. Kirksey, of Denver, president and general manager of the Kirk M. & M. Co., for a grant to a millsite and water rights. Mr. Kirksey promises to have the mill running in six months.

Sinking will be started next week on the Headlight shaft, American Sisters mine, which has been unwatered to the 300-ft. level. [illegible] is manager.

Richards & Co., leasing the Seven-Thirty mine on the Republic vein, is shipping to smelters, the ore bringing, it is said, 375 to 425 oz. silver per ton.

Georgetown, July 28.

(Special Correspondence.)—Work on the [illegible] property, [illegible], has been resumed through the Tunnel and [illegible]. Machinery is being installed at the New [illegible] mine. [illegible] will start in 60 days.

Idaho Springs, July 28.

GILPIN COUNTY

(Special Correspondence.)—Ore shipments from Central City for June were 40% heavier than a year ago. Development is being resumed on the Maine mine, an early-day producer. Free gold has been discovered at the 150-ft. level of the Pine Cone property in Wide Awake district. New machinery recently was purchased.

Central City, July 26.

At the Mountain Monarch mine, at Perigo, an ore-shoot assaying over $170 per ton was discovered while sinking the shaft. Assays of ore from stopes above the adit-level showed returns of $14 to $22 per ton.

The Pierce M. Co. has discovered a good vein 42 ft. below the 400-ft. level in the Pierce mine, Lake district. Frank Hardy is manager.

G. W. Adams, manager of the National mine, below Black Hawk, is experimenting with a Dietz 2-hp. electric drill, operated from a 5-hp. motor. So far the results have been satisfactory.

Sinking on the Chase mine, Willis gulch, has been suspended, owing to an increased flow of water.

The Pittsburg mine recently shipped two lots of ore, of which the first carried 12.24 oz. gold, 12.80 oz. silver, and 14.50% copper, and the second 3.4 oz. gold, 6.56 oz. silver, and 4.20% copper. The 800-ft. level has been cleaned out and retimbered, and stoping and raising from this level has been commenced.

In a report for the Frontenac-Aduddell mill, S. B. Tyler, superintendent, gives the following statement of mill and mine costs for May, when in 29 days 5700 tons of ore was treated: Labor, cost per ton, 44c.; power, 20c.; supplies, 1c.; maintenance, 3c.; assaying, 4c.; superintendence, 1c.; total, 73c. The mill and mine, which are at Black Hawk, are owned by the Frontenac Con. Mines, Ltd., an English concern, and the mill, started in March, is said to mark a new era in the treatment of the low-grade sulphide ores of that district.

IDAHO

OWYHEE COUNTY

Press reports state that the Kittie Burton M. Co., at Indian creek, is taking $10,000 a month from mill plates, and that the run for the past four months totals $40,000 in bullion. A carload of concentrate sampling $40 per ton is reported shipped from the property.

An air-pass line is being placed in the upper levels of the Rainier mine.

SHOSHONE COUNTY

Hecla Mining Co., operating at Burke, paid its ninety-seventh dividend of $20,000 at the rate of two cents per share on July 20. One hundred and ten thousand dollars has been disbursed since January 1, 1911, and $2,220,000 to date. The company is a Spokane corporation with a capital of $250,000, divided into 1,000,000 shares of the par value of 25 cents each. James F. McCarthy, of Wallace, is president.

SHOSHONE COUNTY

On Friday, August 4, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 167, of $65,400, making the total amount of dividends paid $12,898,050.

MICHIGAN

HOUGHTON COUNTY

The annual report of the Calumet & Hecla M. Co. shows its total assets to be $9,150,754; liabilities, $582,897; surplus $8,576,856. The refined copper output for the year ended June 30 was 71,476,881 lb., against 72,108,577 lb. in the previous year, and 82,816,230 lb. for the year ended June 30, 1909. The refined copper output was the smallest in 17 years. The ore stamped amounted to 2,795,514 tons at a mine cost, exclusive of construction, of $1.92 per ton. The report, in regard to stamp-mills, states: "Experiments which have been conducted on a commercial scale for the past two years have demonstrated that the conical pebble mill has a greater capacity, and, on account of grinding finer, permits of greater extraction in treatment of conglomerate sand than the Chilean mill, with which the present re-crushing plant is equipped. The grinder mill also permits of much cheaper construction, and plans are now being prepared for a re-crushing plant with pebble mill. Experiments have also shown that sand lying in Torch lake can also be treated at a substantial profit. The proposed re-crushing plant will have a capacity of about 3000 tons per day."

MONTANA

Fergus County

Kendall Mining Co., owning a mine of the same name at Kendall, controlled by Finch & Campbell, of Spokane, paid its regular monthly dividend of two cents per share, or $10,000, on July 20. The disbursements this year amount to $70,000, and the total to date, $1,595,000. The capital is $500,000.

Work has been started with drilling machines to prospect 400 acres of placer ground on Libby creek, in the Libby district, to test its adaptability for dredging purposes. J. Y. Ownbey and G. F. Hinton, representing outside capitalists, have charge. There is a large acreage of ground on Libby creek which, it is believed, will prove suitable for dredging.

(Special Correspondence.) R. H. Wing, president of the New Victor-Empire Mining Co., has returned to Spokane after having let a contract for the extension of the tunnel 250 ft. on the company's property on Granite creek, ten miles south of Libby, to N. W. Murray, of Butte. The price to be paid is $8 per foot. The tunnel in which he will work is now in 1088 feet.

The object in driving the tunnel is to get under a big iron capping which is found on top of the mountain and which can be traced for 1200 ft. down its side. It is 24 ft. wide. In this iron capping ore has been found in small quantities which goes as high as $700 per ton in silver, and this same character of ore has been found in the lower workings.

The company has an air-compressor, operated by water-power, and has sufficient capital to carry out the present plans.

Libby, July 30.

Silverbow County

The Butte & Superior at Butte is planning to put in a 500-ton concentrating plant to treat its ore, which now is shipped to a custom smelter eight miles from Butte. C. M. McNeill and D. C. Jackling are inspecting the property.

Paul Walcott and W. J. Dason, of Butte, have taken an option on the Black Friday mine, Radersburg district.

NEVADA

Elko County

The Gold Circle Crown M. Co. is planning to extend the west adit to meet ore-shoots believed to be beyond the point reached. The adit is now 500 ft. in the hill. The company expects soon to build a mill. S. M. Levy, of Salt Lake, is general manager. The claims are patented, according to press reports.

Esmeralda County

Eleven bars of gold bullion, valued at $283,100 and weighing 1115 lb. recently were shipped in one day by the Goldfield Con. M. Co. to the Selby smelter at San Francisco. Two of the bars weighed 123 lb. apiece and were valued at $31,300 each. The smallest bar was valued at $19,800. The shipment was sent under double guard. The bars had the highest average value of any shipment sent by the company on any one day.

(Telegraphic Correspondence).—Estimated July production of the Goldfield Con. M. Co., 29,174 tons; gross value recovered, $790,000; operating expenses, $220,000; net profit for month, $570,000. Mines are looking well.

Goldfield, August 2.

(Special Correspondence.)—Announcement is made of the formation of a $10,000,000 company, known as the Goldfield Deep Mines Co., and incorporated under the laws of the State of Washington, which has purchased the control and treasury stock of the Goldfield Merger Mines Co. and will at once begin development by sinking a 4-compartment shaft to a depth of 2000 ft. The project has the financial backing of former Senator William A. Clark, of Montana, whose brother, J. Ross Clark, of Los Angeles, head of the Clark railroads, is the president of the new company, its other officers being C. O. Whittemore, vice-president and general counsel of the same roads, with John Erikson, of Seattle, former president of the Merger Mines Co., and C. F. Redman, general agent of the railroads, additional directors. This news comes as the fruition of recent reports that Clark and others were negotiating for the control of Merger Mines, and sets at rest other rumors, discredited in this correspondence, that W. A. Clark and F. M. Smith were about to combine in the acquisition of the Merger control upon a partnership basis, a highly improbable situation in view of the rivalry in business and conflicting interests of the two men. In a statement made here Mr. Whittemore said that the Goldfield Deep Mines Co. is to be a holding corporation, and the operations of the Merger company and of other companies of which it may secure control will be conducted independently of the Deep Mines Co. The latter has purchased the entire treasury stock of the Merger company, paying the sum of $250,000 into the treasury of the latter, or about 30c. per share. The Merger Mines Co. has been reorganized with C. O. Whittemore as president, John Erikson, Claude Smith, John M. Grace, and W. H. Comstock, directors. In addition to 3,000,000 shares of Merger Mines stock, the Deep Mines Co. has 3,967,000 shares of its own stock in treasury, with which to acquire additional stock of the Merger and stock of other mining corporations. Stock of the new company will be exchanged share for share for outstanding stock of the Merger company. It is said that the new deep shaft will be sunk at some distance from the old 600-ft. shaft and on the Moonshine claim. The Merger Mines Co. was a consolidation of the St. Ives, Velvet, Potlatch, and Gold Horn companies, the territory owned comprising 138 acres. The St. Ives is patented and the rest are surveyed for patent. A considerable quantity of rich ore has been produced by lessees from above a depth of 250 ft. The ground is in a solid block and is bounded by claims of the Consolidated Mines Co., the Florence, Jumbo Extension, Atlanta, Blue Bull, Lone Star, and Spearhead.

Goldfield, August 1.

L. L. Mushett, of Tonopah, and several associates will soon commence operation on a lease obtained from the Manhattan Con. M. Co., covering the main working shaft.

Nye County

(Special Correspondence.)—The North Star Co. has commenced driving from the 950 and 1250-ft. levels to open the ore supposed to exist beyond the fault. On the 950-ft. level the stope exposed 18 in. of ore for a distance of 80 ft. until cut off by the fault. A raise will be made from the top of the stope along the hanging wall of the fault. This is expected to result in recovering the vein. From the 1250-ft. level a cross-cut is being driven to penetrate the Mizpah fault, estimated to run 30 to 40 ft. thick. In the upper levels good ore continues to be developed. The West End is sending out east and west drifts from the 500-ft. level. At the Big Four mine, at Manhattan, the shaft is being sunk to the 400-ft. level with three shifts employed, and from this point drifts will be sent out to the vein. On the 300-ft. level the lessees state the vein is 5 to 10 ft. wide, with 4 ft. averaging $50 per ton. The rest is said to run $15 per ton. Because of lack of milling facilities the lessees have been forced to cease the treatment of their ore, the custom mill having contracts for the handling of ore from other properties. The Tarash lease on the Big Four has its shaft down 90 ft. A whim has been installed, and sinking will continue to the 150-ft. point, from which cross-cutting will be conducted. The Watson lease is also sinking to open a diagonal vein. It is stated that the Big Four company will pay a dividend early in August, the second of the year.

Tonopah, July 28.

NEW MEXICO

DONA ANA COUNTY

Development work on the Memphis mine, near Las Cruces, will be started soon. M. J. Dailey is manager.

GRANT COUNTY

Press reports state that the Lanumex M. Co., operating near Hachita, has discovered a rich vein of lead-silver ore at a depth of 30 ft. The vein is 3 ft. wide and high grade.

SOCORRO COUNTY

(Special Correspondence.)—The product for the first half of July of the Socorro mines amounted to 15,000 oz. gold and silver bullion and 5 tons of high-grade concentrate, from an ore treatment of about 1800 tons. In addition to the average product from all the stopes, high-grade ore is now being mined between the third and fourth levels. An order has been placed for three De La Vergne high-compression oil engines of a combined capacity of 540 hp., for October delivery. These will be installed at the mine and mill, thus avoiding a 3-mile transmission loss over the line from Whitewater. The large wood reserve at the latter point will be used only in cases of emergency after the oil engines are placed in regular commission.

The Ernestine Mining Co. has also placed an order for three De La Vergne oil engines, which will be delivered about the same time as those of the Socorro mines. On August 1 the preliminary work of grading, foundations, etc., for this equipment, will be started and everything will be ready to receive the machinery on its arrival. The company continues paying dividends regularly, the third within four months having been recently disbursed. At the Deadwood mines the mill is now exceeding all past records in tonnage treated, having practically doubled its output within the last three months. At the Gold Dust mines work is progressing steadily with three shifts in the lower tunnel, and a good rate of advance is being made. Good ore is being found in the drifts from the new shaft of the Maud Mining Co. The Mogollon Gold & Copper Co. is making a raise from the east drift in Little Charlie in good ore.

Mogollon, July 28.

OREGON

BAKER COUNTY

Anthony Mohr has closed a deal for the sale of the Bi-Metallic mine in the Greenhorn, Oregon, district to a Portland syndicate. The price was not made public. The property was owned by Andrew Larson. More than 1000 ft. of underground prospecting has been completed. The new owners will drive a cross-cut tunnel to give an added depth of 300 feet.

JOSEPHINE COUNTY

As a result of the Southern Oregon and Northern California Mining Congress, recently held here, a movement has been set on foot to obtain for mineral prospectors the right to kill buck deer for actual use at any time. Other projects urged by the convention were: a permanent organization of the Congress, in harmony with the American Mining Congress and the Oregon State association; a request for co-operation from Alaska and Washington for a square deal for Alaska and other parts of the West; opposition to the policy of the department in the arbitrary withdrawal of lands from mineral entry; the completion of the geological survey of Oregon with regard to mining districts; re-adjustment of railroad rates to aid mining; increased appropriation for the Federal Mining Bureau. The next session will be held at Medford January 17 and 18.

UTAH

SALT LAKE COUNTY

The Alta Consolidated Mining Co. has been organized by Tony Jacobson and associates of Alta. It has 11 claims, of which several are patented, in the upper part of the Alta district in the Wasatch range. It is capitalized at $300,000, divided into 300,000 shares, par value $1 each. Modern machinery will be secured at once for equipping a mill. The company's board of directors include Mr. Jacobson, president; J. H. Winwood, engineer, vice-president; V. S. Snow, secretary and treasurer; A. O. Jacobson, superintendent; and H. Wonder. Silver, lead, copper, and gold have been found in this one-time abandoned district.

The Utah Mines Coalition Co. expects to ship within a month 40 tons of ore daily from its mine in the Big Cottonwood district. R. H. Strickland is general manager. The main raise, it is reported, has advanced 100 ft. in good ore, and will soon connect with the old workings.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—Smelter returns for the San Poil Con. M. Co. show 127.9 tons treated, assaying $3814. Freight and treatment charges were $996, leaving a net return of $2818, or $22 per ton. Two cars shipped later assayed $26 per ton in gold and $7 in silver.

As soon as the air-pipe can be laid from the San Poil mine power-house to the Trade Dollar mine, the latter will be opened. The company soon will be in the market for a new hoist, etc. Address the San Poil Con. Co., Republic.

The Illinois Copper & Silver M. & M. Co. has purchased machinery for resuming work on the Illinois group in August. J. D. Davis, superintendent, is on the ground.

Republic, July 25.

(Special Correspondence.)—The Ben Hur Leasing Co. has on the first level 600 tons of ore broken and awaiting milling treatment which assays about $10 per ton.

At the Surprise mine from a point 280 ft. down the main incline shaft a cross-cut is in 40 ft. toward the vein, which it will intersect at a vertical depth of 300 ft. It has 72 ft. farther to run. A big breast of $8 to $10 ore has been found just north of the Jim Clark adit. From No. 2 raise to the winze intermediate level a 200-ft. drift has intersected eight or nine feet of the vein, and in driving on it 150 ft. the ore samples assayed from $10 to $160 per ton, but neither the hanging nor foot-wall has yet been touched.

At the Black Tail mine, on the adit level, 15 ft. north of the winze, the ore on a cross-vein, just broken into, assays $132 in gold and $18.70 in silver, total $150.70 per ton.

Republic, July 28.

STEVENS COUNTY

(Special Correspondence.)—A vein of galena 14 in. wide has been discovered at the Butte & Washington mine.

The Alice E. mine will be in the market soon for machinery, including a diamond-drilling outfit. Address, George Robertson, manager, Orient, Stevens county.

Orient, July 25.

CANADA

BRITISH COLUMBIA

A 2-ft. vein of solid ore has been discovered at the 1200-ft. level of the Rambler-Cariboo mine, W. E. Zwicky, manager. Two other veins will be met soon, it is believed. A mill will be built when the route of a proposed branch of the Canadian-Pacific from Three Forks to Bear Lake is known. A. F. McClaine of Spokane is president.

At the Standard the orebody has been found in the No. 6 adit-level, which is 240 ft. below the No. 5 level, where the most extensive work has been done in the big ore-shoot.

T. Walter Beam of Denver, representing the shareholders of the controlling interest in the Hedley Gold mines and the Nickel Plate mine, has secured an option until September 1, on the Nugget mine in the Sheep Creek district.

ONTARIO

(Special Correspondence.)—Despite the Porcupine fire the ore shipments for 1911 will not be less in value than in 1910. The fact that higher-grade ore on the average has been shipped and that considerable bullion has been sent out, will make up for the discrepancy and bring the total valuation above that of last year. A statement issued by the La Rose on July 1 shows cash in bank and value of ore in transit and at smelter, $1,184,242; ore sacked for shipment, $162,311; total, $1,346,553. Half of the output now comes from the Princess and Lawson properties. At the Princess an orebody 8 in. wide carrying 4000 oz. per ton has been found at a depth of 250 ft. in a winze sunk from the 250-ft. level. Good ore is being extracted from the roof of No. 8 stope at the Lawson property. Work will shortly be begun on the Violet property, the old shaft of which is being unwatered. A statement of the condition of the Nipissing on July 1 shows cash in bank, [illegible], ore in transit and at smelters, $464,118, ore sacked for shipment, $251,957; total, $1,419,280. The Coniagas has declared a dividend of 6%, with a bonus of 3%, making 27% in all for this year. The Crown Reserve has issued a statement for the six months ending with June, which shows a production of 1,482,904 oz. of silver at a profit of $654,287. After paying a royalty amounting to [illegible], the amount of $530,641 was distributed in dividends, at the rate of 30% for the half year. The Temiskaming has issued a statement showing a surplus of $309,951 on July 1. The general manager reports that at the west of the property, underground operations have met the pre-Cambrian diabase formation, which is entered by vein No. 4 with apparent loss of valuable ore, although as yet there has not been sufficient work done to prove definitely whether ore occurs in this formation or not. Veins No. 1 and 3 are being opened up at the 575-ft. level without any indication of a change from the Keewatin formation, and some rich ore has been found in patches. It is hoped that when the ore-shoot now being mined on the 500-ft. level is reached at the lower depth, good ore will be obtained. Two good veins have been found at the Ophir. One of them averages 2 ft. in width and yields good concentrating ore. The other, about 500 ft. distant, is 3 ft. wide. This mine is likely to become a producer in the near future.

Toronto, July 28.

(Special Correspondence.) The Porcupine G. M. Co. will immediately construct a 100-ton mill and a power-plant, plans for which, drawn up by C. H. Poirier, manager for the company, have been approved by the directors. An eight-drill compressor, with boilers, drills, and a new hoist, will be ordered.

The main shaft will be sunk to the 200-ft. level, where cross-cuts will be run to tap the No. 2 and 3 veins. The latter, found just before the fire at the 100-ft. level, is 18 ft. wide, and assays from wall to wall, according to report, more than $15 per ton. The wall-rock also carries milling ore. Drifts will be driven on the No. 3 vein 90 ft. to a shaft which has been sunk to a depth of 65 ft. on the vein. About 451,000 shares of treasury stock remain unissued. The company has ample funds on hand.

Cobalt, July 27.

The Oliver Silver M. Co., Ltd., has let a contract to sink a 100-ft. shaft on its property near Calcite lake, Montreal River district. The company has five claims, and in the course of assessment work three or four veins showing native silver were discovered.

The Philadelphia Syndicate, organized to rehabilitate the Cobalt Central M. Co. and to take the Standard Co. out of liquidation, has issued an appeal to shareholders to take stock in the new organization so that work may be resumed. The property purchased includes 200 acres, patented, and a 100-ton concentrating mill. The Powell, Big Pete, and other mines are on the property.

The Plenaurum Mines, Ltd., headed by W. S. Edwards, of Chicago, which controls the Western Armstrong-Booth claims, has been capitalized at $2,500,000 in 500,000 shares. Of these, 100,000 will be issued in Canada. It is reported 50,000 have been subscribed in London.

YUKON

In an informal talk with representative Dawson citizens July 13, F. T. Congdon, member of parliament (for Yukon affairs) stated that it is believed some workable plan may be devised whereby the poor man may acquire large grants of dredging ground. Press reports state that he intimated that the features objected to in the former concessions would be eliminated in the proposed large leases. A miner's license covering any number of claims without increased fee may be adopted. He stated that with both the United States and Canada it is becoming the settled policy to grant only leases, not patents for mining properties. Representation would apply under all leases, and in default the property would revert to the Government. No rental charges would be made on placer claims. The new code is to apply where the Federal Government has full authority, including Yukon and all other territories, parts of British Columbia, and parts of one or two other provinces. All mining laws are to be made uniform. The mining act is to have five divisions relating to general mining, placer, quartz, oil and petroleum, and, finally, probably water and gas. The act is to be automatic. Mr. Congdon heartily endorsed reciprocity and was pleased at the growing good feeling between the United States and Great Britain.

PHILLIPINE ISLANDS

BENGUET

(Special Correspondence.) The 10-stamp mill of the Headwaters M. Co. is ready to commence operations. Besides 1100-lb. stamps, the mill is equipped with Hardinge conical tube-mill, Callow dewatering cones, Frenier pumps, two Pachuca tanks, and a Ridgway filter. Amalgamation is not employed, the process of extraction being an all-cyanide one. The company expects to treat 60 to 70 tons per day slimed to 150 mesh. The mill-heads will average $9. C. T. Durell is superintendent and G. Weedon mill foreman.

Plans have nearly materialized to put the Benguet Con., at one time the leading producer of this district, once more in a position to do justice to its ore deposits. This company has been more or less crippled since the big *baguio* of 1909 carried off its cyanide plant. Fortunately, the upper part of the mill was left standing, though the concentrating tables and all below them were carried away. By cutting expenses almost to a vanishing point and choosing the best of the ore, Nels Petersen, the manager, has been able to keep things going, though the ore only plates 40% of the assay values. A few days ago the Consolidated company shipped a bar weighing 172 oz. to Manila, the output of the little 6-stamp mill for the past month.

HEADWATERS MILL.

The Major mines have been pegging along with their 6-stamp mill, testing out the various ores on their property, which is a large one. They are now erecting a 30-ton cyanide plant which they hope to have completed next month. The plant was designed by Huxley St. John Brooks, the company's metallurgical engineer, who is in charge of construction.

Baguio, June 15.

MEXICO

HIDALGO

The reorganization of the Santa Ana y Anexas Co. of Pachuca, say press reports, is almost completed, and ore extraction will be started in the near future. A new skip-road and head-frame have been built and the main shaft has been secured with masonry and retimbering. A Westinghouse motor of 225 hp. will supply the motive power.

SONORA

A report just issued by the Creston Colorada company at Torres, states that the mill in the past five months has crushed 82,300 tons, at an average cost of $3.40 per ton.

Company Reports

PORTLAND GOLD MINING CO.

The seventeenth annual report of this company, which operates mines at Cripple Creek and mills at Colorado Springs and Victor, Colorado, shows that during the year ended February 6, 1911, 67,515 tons of ore was mined and shipped to the mills at Colorado Springs. This ore had a gross value of $1,241,168, or an average of $18.32 per ton, and was mined and milled at a net cost of $987,042, leaving a profit of $367,380, as $113,254 was recovered by the new mill at Victor from ore that was formerly regarded as waste. Miscellaneous income increased the profit to $373,501. As depreciation upon mines and mills, $241,871 was allotted, and $240,000 was paid in dividends, leaving a balance to be carried to the 1911 account of $2,402,105. The cash on hand January 1, 1911, amounted to $134,849. During the year $136,632 was spent upon the construction of the new mill, built at Victor at an elevation of 10,400 ft. This has a capacity of 350 tons per day, and is so nearly automatic that in addition to the metallurgists, machinists, and electrician, only four men are required to operate the plant at full capacity. It was first designed to treat the dump ore, but as the present daily production of waste is nearly equal to the capacity of the mill and can be delivered to the mill at the same cost as placing on the dump, it is used as mill-feed. The ore as taken from the mine is much harder than that on the dump, and in order to crush the tonnage for which the mill was designed it was necessary to install an additional Chilean mill. One man with an electric larry transports from shaft No. 2 to the mill, 1000 ft. distant, all the ore the mill can treat in 24 hr. Arrangements will be made later to withdraw large quantities of waste that have been used as filling for stopes, replacing it by tailing from the mill. The work of the mill during the past six months has demonstrated that the low-grade ore can be successfully treated by the Portland process at a good profit. It is probable that the mill will be increased to a capacity of 500 to 700 tons per day within a year or two. The Portland G. M. Co. is capitalized for $3,000,000 in 3,000,000 shares. The gross production of the company to date has been $31,262,515, and dividends have been paid aggregating $8,677,080. The Portland is one of the best known companies of the cripple Creek district, and is notable for the large profits made and the skill and good management shown in its operations.

UNITED STATES SMELTING, REFINING & MINING COMPANY

The fifth annual report of this company, with which is affiliated the U. S. Smelting Co., The Needles M. & S Co., The U. S. Mining Co., the Centennial-Eureka M. Co., the Richmond Eureka M. Co., the Mammoth Copper Co., Compania de Real del Monte y Pachuca, the U. S. Stores Co., the U. S. Metals Ref. Co., and the International Metals Selling Co., shows that for the year ended December 31, 1910, the earnings of the companies, after charging cost of production, selling expense, and repairs, were $3,738,541. From this, $1,067,069 was deducted for depreciation, improvement, and reserve, and $187,154 for administrative and legal expense, leaving a net profit of $2,484,318, which, added to the undistributed surplus of $1,715,231 from the previous year, amounts to $4,199,549. Of this, $852 has been applied as dividends on the minority stock of subsidiary companies, $1,701,701 as dividends on the preferred stock of the U. S. S. R. & M. Co. at the rate of 7% per annum, and $702,101 as dividends on the common stock at 4% per annum, leaving an undistributed surplus of $1,794,895. In the balance sheet the cost of the properties is given as $41,577,092, against which have been issued 351,103 shares of common stock at $50 each, with $175 scrip, and 486,320 shares of preferred stock, of $50 each, with $250 scrip. The report concludes with brief summaries of the operation of the subsidiary companies for the year.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

LOCATION OF MINING CLAIM IN FOREST RESERVE.—USE OF SURFACE FOR SALOON

The location of a mining claim within a forest reserve does not operate to withdraw the land embraced therein from the jurisdiction of the Secretary of Agriculture, nor does it give to the locator, acquiring possessory interest only, any authority to use the surface for the erection and maintenance of a saloon without a permit from the Secretary of Agriculture.

United States *v.* Rizzinelli, 182 Federal, 675, August 1910.

LOCATION OF MINING CLAIM IN FOREST RESERVE

The United States statutes permit any person to enter upon the forest reservations for the purpose of prospecting, locating, and developing the mineral resources thereof, provided such person complies with the rules and regulations covering such forest reservation. The statutes also provide that any mineral lands in any forest reservation shall be subject to location and entry under existing mining laws. It is also provided by statute that the claimant shall have the exclusive right of possession and enjoyment of all the surface of any claim, and of all veins, lodes, and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines, extended downward vertically. Under these statutes the rights of a locator of a mining claim within the boundaries of a forest reserve are substantially the same as those of one who locates a claim upon the public domain. Under these statutes the question has arisen as to the meaning and construction of the clause providing that "the claimant shall have the exclusive right of possession and enjoyment of all the surface." In passing upon this particular question a Federal judge in the District of Idaho said substantially that the Government confers upon a locator the right of possession and enjoying the surface of a mining claim for mining purposes without the payment of any consideration whatever, and offers for a small consideration to convey to him the entire estate. It gives the mineral to him who finds it, and, for purposes incident to the extraction thereof, permits him to possess and use the ground in which it is found. It does not give him the ground, but empowers him to purchase it, and he may do so if he desires its permanent and unrestricted use. But the statute gives the locator nothing but the right of present and exclusive possession for the purpose of mining. It does not divest the legal title of the United States, or impair its right to protect the land and its product. The two titles recognized by the Government confer totally different rights. One confers the right of the locator to the possession of the land for the purpose of carrying on his mining operations as long as he performs the required conditions. Subject then to the locator's legitimate use for mining purposes, the Government continues to be the owner of the land and is interested in conserving its value and preventing injury and waste. It therefore follows that forest reserve lands embraced in a mining claim continue to constitute a part of the reserve, notwithstanding the mineral location, subject, of course, to all legal rights and privileges of the locator. The paramount ownership being still in the Government, and it also having a revisionary interest in the possessory right of the locator, the Government accordingly has a valuable estate which is necessarily a substantial property right of the Government. Under this construction the locator's rights are not curtailed; there is no intrusion upon his possession; his right of enjoyment is not necessarily qualified or infringed by the intention of the forest reserve. He may possess and utilize the entire claim, including the surface, for all purposes and to the same extent for and to which he could have possessed and used it if no forest reserve existed.

United States *v.* Rizzinelli. 182 Federal, 675. Aug. 1910.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Z. CUSHING is at Juneau.

C. H. PEARCE is at Cordova.

F. L. SIZER is in San Francisco.

S. W. MUDD is in San Francisco.

M. D. SHIPMAN has gone to Ouray.

FRANCIS DRAKE is in San Francisco.

F. G. CLAPP is at Pittsburg for a few days.

G. H. GARREY has returned to San Francisco.

W. W. MEIN is now residing at San Francisco.

JOHN W. YOUNG was in San Francisco last week.

C. W. EVANS, of Virginia City, Nevada, is in San Francisco.

M. D. DRAPER is at Chitina, Alaska, for the Hubbard-Elliott syndicate.

FRANK BERRY, of Fairbanks, Alaska, is at the St. Francis hotel, San Francisco.

H. A. KELLAR has been examining the Mother Lode mine at Kennicott, Alaska.

F. W. TRAPHAGEN has been at Tacoma and San Francisco for the U. S. Bureau of Mines.

R. S. TARR and LAWRENCE MARTIN went in to Fairbanks, Alaska, from Cordova in July.

F. H. PROBERT is making an examination of the Begoles Mines Syndicate at Goldfield, Nevada.

J. B. UMPLEBY has gone to Idaho for this summer's field-work with the U. S. Geological Survey.

J. F. B. ERDLETS has been examining prospects in the McKinlay Lake district near Cordova, Alaska.

COURTENAY DE KALB has been investigating the San Antonio mine, San Antonio de la Huerta, Sonora.

H. G. WALKER and B. C. STANNARD, who have been visiting southwestern Alaska, have returned to Tacoma.

R. B. BRINSMADE left St. Louis recently for Mexico, where he will spend several weeks in various mining camps.

HEINRICH RIES was at Glacier, B. C., during the week and has gone to Vancouver, on his way to San Francisco.

HORACE H. HOWARD, consulting engineer for the Globe Exploration Co., New York City, is in the Porcupine district.

GEORGE J. HOUGH, metallurgist and chemist of Denver, recently purchased the leading assay office at Salida, Colorado.

JOHN B. CLEVELAND is to take over the management of the West Dome, succeeding R. A. WEISS, who lost his life in the fire at Porcupine.

H. A. ROESLER, a graduate of the Missouri School of Mines in the class of 1903, has been appointed instructor in metallurgy and ore-dressing at that institution.

JOSEPH A. HOLMES, director of the Bureau of Mines, left Washington July 5 for a trip to the Pacific coast and then on to Alaska. He was in San Francisco, but has left for Juneau, Alaska, and will return to Washington within two months.

D. A. MCMILLEN, chief consulting engineer for the Globe Exploration Co., New York City, is spending a few weeks in central and southern Mexico examining properties for the interest of the company.

B. A. SEITZ, one of the heaviest owners of the Lucky Tiger mine, Sonora, was seriously wounded recently at Kansas City. While taking a walk he was hit by a bullet fired into the crowd by a fleeing diamond thief.

Obituary

LINTON B. SUTTON, one of the well known mining engineers of America, died in New York on June 11. He was born at East Liverpool, Ohio, in 1866, and graduated from the Michigan College of Mines in 1889. For nine years his work was in the Lake Superior district, where he had experience in mining on a large scale, and made a reputation as a thoroughly competent mine manager. This led to his being invited to join the engineering staff of S. Neumann & Co., where his first commission was to examine the copper deposits in Namaqualand. Completing that work, he went to Johannesburg, and eventually became general manager for the Randfontein Deep, Ltd. Later he was engaged in important gold-mining investigations in Madagascar, after which he returned to Johannesburg, and for a brief period was acting consulting engineer for the East Rand Proprietary Mines. Mr. Sutton returned to the United States in 1907 and in March 1909 became assistant to Pope Yeatman, consulting engineer for the Guggenheim Exploration Co., taking part in the development of the Nevada Consolidated, Copper River, Esperanza, and other important mining enterprises. In 1910 Mr. Sutton was made consulting engineer for the Esperanza Mining Co., which position he held at the time of his death. A thoroughly lovable man, he was warmly appreciated in his profession, in which he had many admirers and friends.

Recent Publications

MINERAL RESOURCES OF WYOMING. Bulletin 1, Series B. By C. E. Jamison. 102 pp. Cheyenne, 1911. This little volume, compiled from various sources, chiefly the bulletins issued by the late W. C. Knight, is a brief summary of the mineral resources of Wyoming, more than one-half of the pages being taken up by a reprint of the mining laws of the United States.

MEDELLIN, EL 20 DE JULIO DE 1910. Published by *la Sociedad De Mejoras Publicas*, in commemoration of the first centenary of the independence of the Republic of Colombia. N.p., n.d. This handsomely illustrated and printed volume, issued in Spanish, French, and English, will surprise many citizens of the United States, who are accustomed to think of Colombia as a land of forest and streams, inhabited by a sparse population dependent upon agriculture for a livelihood. To all such the photographs of cotton spinning and weaving mills, chocolate manufactories, and a host of other industries will be something of a revelation.

The following publications of the Bureau of Mines have recently been received: 'Apparatus and Methods for the Sampling and Analysis of Furnaces Gases,' by J. C. W. Frazer and E. J. Hoffman; Bull. 12, pp. 22, ill., 1911. 'Fees for Testing Explosives,' Schedule 1, pp. 6, June 1, 1911. 'Briquetting Tests of Lignite,' by C. L. Wright; Bull. 14, pp. 64, ill, 1911. 'Sampling of Coal in the Mine,' by J. A. Holmes; Technical Paper 1, pp. 18, ill, 1911. 'The Escape of Gas from Coal,' by H. C. Porter and F. K. Ovitz; Technical Paper 2, pp. 14, 1911.

The issuing of a series of 'Technical Papers,' of which the first two are listed above, is a most commendable innovation. In the carrying on of research, many details of minor importance are necessarily investigated, which, not being directly related to the main subject, can not properly be included in the principal report. Unless published in technical journals, as is sometimes done, the results of such work are practically lost to the profession, but when sent out in the form of brief papers, will undoubtedly be of great assistance to other workers. It also furnishes an excellent means of giving out preliminary reports of progress, and is a further evidence of the desire of the Bureau of Mines to be of service, both prompt and effective, to the mining industry.

L. Vogelstein & Co. report the following figures of German consumption of foreign copper for the months January to June, 1911:

	Tons.
Imports of copper	90,281
Exports of copper	4,093
Consumption	86,188

as compared with consumption during the same period in 1910 of 79,488 tons. Of the above quantity 78,454 tons was imported from the United States.

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked*.

	Min.	Max.
Antimony ore, 50%, per ton	*$20.00	$25.00
Arsenic, white, refined, per lb	0.01¾	0.02¼
Arsenic, red, refined, per lb	0.06¾	0.07¼

Carnegie Steel Co., Pittsburg, Pa. 'Steel Mine Timbers' with data and tables for the use of mining engineers. 32 pages. Illustrated. 10 by 8¼ inches.

Pacific Tank & Pipe Co., San Francisco, Los Angeles, and Portland. 'Wooden Pipe, Its Many Advantages.' Illustrated. 24 pages. 4 by 8½ inches.

Lane Mill & Machinery Co., Los Angeles, Cal. 'Press Reports Relating to the Comparative Efficiency of Stamps and Lane Mills.' 12 pages. 6 by 9 inches.

The Behrend Concentrators. New York City. Bulletin No. 3. 'Pneumatic Dry, Wet, Multiple, and Flotation Concentrators.' Illustrated. 12 pages. 6 by 9 inches.

Trenton Iron Co., Trenton, New Jersey. 'Wire Rope.' 80 pages. Illustrated. 6 by 8 inches. Tables, formulas, etc., useful for operations involving the use of wire rope.

The Goulds Manufacturing Co., Seneca Falls, New York. Bulletin No. 105, 'Single Stage, Single Suction Centrifugal Pumps.' 16 pages. Illustrated. 8 by 10 inches.

Henry R. Worthington, 115 Broadway, New York. Bulletin W-176 A, 'Type "D" Centrifugal Pumps.' 12 pages. Illustrated. Also Bulletin W-185, 'Centrifugal House and Sump Pumps.' 8 pages. Illustrated.

John A. Roebling's Sons Co., Trenton, N. J. 'A Big Rope.' Describing a wire rope three inches thick, made for haulage purposes for the Spanish-American Iron Co. 8 pages. Illustrated. 9½ by 7½ inches.

Carnegie Steel Co., Pittsburg, Pennsylvania. 54 pages. Illustrated. 5 by 7½ inches. Describing steel derricks and drilling rigs for oil, gas, mineral exploration works, etc. Covers most up-to-date drilling methods.

Sullivan Machinery Co., Chicago. Bulletin 66 D. 20 pages. Illustrated. 6 by 9 inches. Describing the Sullivan hammer-drills for use in quarries, including plug-drills, foot-hole drills, and stone-dressing tools.

Ingersoll-Rand Co., New York. Form No. 4003. 'Little Giant Rock Drills.' 16 pages. Illustrated. 6 by 9 inches. Also Form No. 4016, 'Imperial Valveless Telescope Feed Hammer Drill.' 16 pages. Illustrated. 6 by 9 inches.

Allis-Chalmers Co., Milwaukee, Wis. Bulletin No. 1079, 'Steam Turbines and Generators.' Bulletin No. 1415, 'Gates Rock and Ore Breaker.' Bulletin No. 1446, 'Huntington Mills.' Bulletin No. 1624, 'Centrifugal Pumps.' Illustrated. 8 by 10 inches.

Sullivan Machinery Co., Chicago. Bulletin 66 A, 'Sullivan Rock Drills for Excavating Rock'; illustrated; 8 pages; 6 by 9 inches. Bulletin 66 B, 'Sullivan Rock Drill Mountings and Accessories'; illustrated; 24 pages; 6 by 9 inches. Bulletin 66 C, 'Sullivan Hammer Drills'; illustrated; 20 pages; 6 by 9 inches.

Commercial Paragraphs

The **Moore Filter Co.** of New York announces that it has closed a contract with the Hollinger Gold Mines, Ltd., Toronto, Canada, for the installation of a type A Moore filter process equipment for an ultimate capacity of 1000 tons per day. The equipment will consist of two units, each of 500 tons. The equipment for the first unit is now in course of construction.

GOLD is said to have been discovered near Rogers, Arkansas, by a man working under supernatural guidance. It would take some such help to find real gold in the Ozarks, though many good mines of other metals have been found without any mysterious assistance from spirits.

WORKMEN'S COMPENSATION ACTS are having difficulties in threading the mazes of constitutionality. The employers' liability law, enacted by the New York legislature, has been declared unconstitutional, and a similar question has arisen in regard to the law enacted in Washington, the text of which we recently published.

POSTAL SAVINGS BANKS were opened at New York, Boston, and Chicago recently. In Boston 208 accounts were opened with an average deposit of $10.75, and in New York 172 accounts with an average of $22. When the system is thoroughly established it should greatly aid in the forming of the habit of saving among miners, as well as other wage-workers.

INTERNATIONAL CO-OPERATION is pleasingly shown in the recent treaty concluded between the United States, Russia, Canada, and Japan, covering the hunting of fur seals in the northern Pacific and Bering Sea. Sealskins are of such value as to form a potent lure for pelagic hunters, whose depredations bid fair to exterminate the herds. Under the present arrangement Canadian and Japanese hunters will have scope for their activities, and the herds will be protected.

MICHIGAN COLLEGE OF MINES has been celebrating its twenty-fifth anniversary, and its quarter century of good work is well worthy of celebration. We printed last week an account of the plans for the occasion, and in this issue we publish the address of Mr. George Otis Smith, director of the United States Geological Survey, who appropriately chose for his subject the relation of the Survey to the public lands. We hope to print others of the addresses delivered, for notable occasions give rise naturally to notable discussions.

GOLDFIELD is, properly enough, much elated at the report that the Goldfield Merger Mines Company is to undertake deep development. The area controlled by this company is well situated and includes the St. Ives, Velvet, Gold Horn, and other properties in which good ore has been mined to a depth of nearly 300 feet. The proposal to sink to 2000 feet is a bit daring, though geologists and engineers familiar with the ground feel confident that workings may be planned which will certainly intersect the veins at that depth. Whether these veins will be found to contain ore of high or low grade can not be predicated, but at least it is a legitimate, even though venturesome, bit of prospecting. The statement that Mr. W. A. Clark is backing the enterprise has created astonishment, since that experienced miner and investor is not known as one who takes risks. Ordinarily, Government bonds, rather than deep shafts in unproved territory, appeal to him. Probably the real principals have not been announced.

COMSTOCK mines, as a result of the discoveries in the Mexican workings, threaten to become again producers of ore rather than assessments. The Mexican company has, in fact, paid a dividend, the first in years, though the mill, now building, will not be ready for weeks. The management is to be congratulated on the improved condition of things. At the same time we are reminded of the fate of a wily Colorado promoter who once in an optimistic moment paid a dividend. Speaking of it afterward, he said it was a horrible mistake, as it created a fairly insatiable demand for other dividends, which ultimately led to his undoing.

WET PROCESSES were used in most of the early American cement mills. Less than twenty years ago it was difficult to get favorable consideration for any property where dry mixing and fine grinding were essential to success. Improvements in grinding apparatus and introduction of the rotary kiln have long since given the advantage to mills using the dry process. In Michigan, where marl and clay are used, wet grinding and updraft kilns are still the rule. A wet slurry, however, is difficult to handle, being too thick to pump and too thin to spade easily. The intermittent kiln is also expensive, and the continuous process of burning is greatly to be preferred. On another page we publish a brief note on the recrudescence of the wet process in Germany, where it is used to meet special conditions of supply of raw material. It does not seem likely that such mills will become common. While in devising a means of using the rotary kiln to burn wet slurry, one of the chief objections to the old mill is removed, the result is not entirely satisfactory, and there is always the mechanical problem of handling sticky material in large quantities.

THOSE who have followed the Sugar Trust investigation, and recall the enmity between Spreckels and Havemeyer and Arbuckle, are wondering if a peaceful revolution has come upon us. To call upon John Arbuckle for his testimony in regard to trade combinations when this picturesque old wrecker, hero of many a financial battle in the Street and many a struggle with wind and wave in his pet pastime of raising sunken ships, was too ill to leave his bed, to carry Federal indictments into the inner circle of the family of Morgan may not seem a matter of wonder to the jaded reader of daily scare heads. But if one of the old guard of the days of McKinley, the late Mark A. Hanna, for instance, could know, he would surely turn in his grave. In the life of Richelieu there came a moment when, against his enemies, he invoked the power of the Church of Rome, and even as his enemies drew back awed, the power that was his passed from him. Today the house of Morgan stands many times multiplied in strength, held far more in fear and awe than ever at any time heretofore, and even with the ripening years, with honors almost worldwide, come prying committees who question the great rewards for the Steel Trust flotation and who insist that our most prominent financiers must testify even as other American citizens. The International Harvester Company, especial creation of Mr. G. W. Perkins, until recently a pillar in the house of Morgan, is to come under scrutiny next. The accusing voices in Wall Street say that Washington is playing politics at the expense of all business progress. On the other hand, observers whose horizon is not limited by Trinity Church at one extreme and the East River at the other, realize that there is a persistent and growing demand, that will not be denied, for the enforcement of measures that will shake off the influence of the closely allied combinations that now control so many lines of human industry.

The Controller Bay Controversy

An unfortunate and bitter word-battle has sprung up over the action of the President in opening to entry certain lands valuable as railway terminals on Controller Bay in Alaska. He is charged with "betraying" the public interest, and he has replied in a lengthy and heated message to the Senate, employing words and phrases quite as vigorous as any that gave tang to the notable communications of his immediate predecessor. Those who recall Mr. Taft's castigation of Mr. J. F. Wallace when the latter resigned as Chief Engineer of the Isthmian Canal Commission, need no reminder of his ability and willingness to use direct language when he thinks the occasion demands. Evidently when writing this message Mr. Taft felt justified.

We count ourselves good conservationists, indeed many of our readers protest that our sympathies lie too strongly in that direction, but in this case we fail to see any adequate cause for so great a storm. While we do not accept the President's evident feeling as to the large amount of "unscrupulous and corrupt misrepresentation of the wicked," we confess to a suspicion that there has been a well engineered effort to put the President 'in a hole.' This is all the more regrettable in that it is entirely unnecessary. No observer of current affairs, friendly or unfriendly to the President, can have failed to note an ability on his part, amounting almost to genius, to 'get in wrong'—to use an expressive colloquialism. He does even the most excellent things in a most unfortunate way, and intensifies popular mistrust even while trying to correct a blunder. This must be remembered in any attempt to interpret his acts.

The facts in the present case are simple and, in the main, are undisputed. The Bering River coalfield, as is well known, lies about twenty-five miles back from the southern coast of Alaska. It contains a large amount of valuable coal, and transportation lines from the mines to the coast are certain to be important and profitable at some time in the future. There are three feasible routes, some of them easily open to more than one line of railway. The Copper River & Northwestern railway, owned by the Alaska Syndicate, has a harbor and terminals at Cordova. It has a survey from Katalla Junction to the coalfield and is prepared promptly to lay the necessary track whenever mines are opened. While this route, from colliery to harbor, is the longest of the three that must be considered, it can be completed with the smallest amount of additional investment. Whatever may be done in regard to other roads this line seems certain to be built, since the demand for coal for the road and for towns and mines along the line will force its construction. A second route is to Katalla Bay. A number of surveys have been made along this route, and the Alaska Syndicate, after expending considerable money on a line to this point, abandoned it. It is the general consensus of opinion of those on the ground that a really safe harbor here could only be constructed at a prohibitive expense. The third route is to Controller Bay. Prior to 1907 this body of water was thought to be too shallow and too unprotected to offer any possibilities worth considering. It was then learned that a deep channel extended up the bay, between Kanak and Wingham islands and back of Okalee spit, to within approximately three and a half miles of the shore. While the detailed map made by the Coast & Geodetic Survey was not available until 1910, enough was known before then to permit a fair appraisal of the worth of the harbor. When Mr. E. C. Hawkins investigated the harbor situation for the Alaska Syndicate and recommended abandonment of the work at Valdez and Katalla and concentration at Cordova, he knew enough about the Controller Bay channel to condemn it. This was before the land had been withdrawn from entry; it then was freely available to anyone who had or could buy certain sorts of land scrip, and there was no conceivable reason why if the Morgan-Guggenheim Syndicate wanted the harbor it should not have been taken. After a study of the whole situation Mr. Hawkins recommended Cordova as the best railway terminus, and work was accordingly centred there and the road was built to the copper mines. It is his opinion of the probable low comparative value of the Controller Bay harbor. Mr. Hawkins was followed by the Army, the Navy, and the Geological Survey, officers from each recommending its abandonment so far as governmental use was concerned. Others refused to accept this conclusion, and among them was Mr. Richard S. Ryan, who organized the Controller Railway & Navigation Company, made surveys to the coalfields, filed on a right of way December 14, 1910, secured the exclusion of the necessary land from the Chugach National Forest, and promptly filed on the maximum amount of land, 160 acres, fronting on the bay. Additional claims supposed to have been made in his interest were made nearby. It is alleged, though denied, that in securing the release of the land he used the personal influence of Mr. Charles H. Taft, and that the withdrawal by executive order rather than by proclamation, gave Mr. Ryan's company, because of prior information, important advantages. This loses point when the President shows that, despite all the publicity since, a large amount of land and frontage still remains available to anyone else who may care to take it. It furthermore seems clear that even granting that Mr. Ryan was favored in the matter, he has no monopoly, nor can he acquire any monopoly of the frontage, because of reservations required by law in favor of the United States. Mr. Ryan's company can even now only reach deep water by means of a pier more than three miles long, which can only be built under a revocable permit issued by the United States Government. There seems also to be no question that the land was not properly forest land; being valuable neither for its trees nor for conserving rainfall. It was included in the Chugach Forest to save the terminals, not to save the trees; and, after having traveled some miles over these coast flats, we are quite disposed to agree that the Forest Service did right in recommending its elimination. It is true that the area might have remained in the Forest and railway and terminals have been built under revocable permit or lease, as the pier must be in any event, but we do not believe that desirable or necessary in this case; the rights of the public being sufficiently guarded otherwise.

Much has been said to the effect that Mr. Ryan is acting in behalf of the Morgan-Guggenheim syndicate. We have already indicated reasons, aside from stout denials on all sides, why this may well be doubted. Our own belief, after having discussed the matter on the ground with men of all shades of opinion, is that Mr. Ryan is not backed by the Alaska Syndicate, but is merely a promoter who sees a chance to get hold of something that will sell. We are further of the opinion that if the Controller Railway & Navigation Company ever carries out its plans and builds a railway, the Alaska Syndicate will be practically forced to buy the line. There is not likely to be enough business for some time to adequately support two railways at low rates, and the plain lesson of American railroad history is that under such circumstances the lines are combined, directly or indirectly, and rates put high enough to pay interest on the whole investment—and an indefinite amount of water. In other words, if the proposed railway be built, users of Alaska coal will have to pay a higher price in the end than if there be only one road. More money will have been invested, and the amount of traffic remaining practically the same, higher rates will be necessary. Recent decisions have placed Alaska railways under the Interstate Commerce Commission, but in fixing rates, whoever does it, the investment must be taken into account. Many times in the past, competing railways have been built to sell, but it is not considered sound public policy to encourage such enterprises. In the general chorus of condemnation raised by this issue, our own protest for fairness to the existing railway will probably be lost, but until there is enough traffic or probability of enough traffic to support two lines, we do not believe in encouraging investment of more capital. The Alaska Syndicate has spent large sums of money to furnish much needed transportation in Alaska. It will have to spend many millions more before any profit can be earned, and, whether it be composed of the Morgan-Guggenheims or of widows and orphans, it should not be exposed to unwarranted and competitive railway building.

Definite Information

Among the most vivid recollections of our youthful days is that of a history teacher, of Celtic ancestry, who, in response to our blundering attempts to explain the causes of the Punic wars, or to outline the Delian Confederacy, would pound the desk and exclaim: "That won't do! I want some definite information!" The experience of more mature years discloses this as the general attitude of mind of the business world, and properly so. Mr. Gradgrind was greedy of facts, but, valuable as facts are, much of their usefulness is lost unless they are shown in their proper relations, and thus become available as information. How rare definite information is can be quickly perceived by the perusal of reports, technical journals, and even text-books. Traced back to its source, this lack of information is usually due either to the absence of accurate observation, or to the omitting to make a detailed contemporaneous record of the facts observed. The temptation is always strong to put off the making of a record until 'a more convenient season'; there is always some obscure point that can be cleared up later, some bit of information that can easily be obtained from some one who is absent, and it is more comfortable and convenient to write notes in the library than in the mine, with the candle guttering on the pages and water drops accurately 'holing out' in the narrow gap between the hat-brim and the edge of the collar. But even the most experienced observer finds, in making his record, that additional observation is necessary to fill in gaps. If the record is contemporaneous, the supplementary observations are easily made and the record becomes complete; the information is definite. Once the survey is closed, the mine left, the district quitted, the opportunity is gone, and there is no recourse except to leave the gaps, or to 'fudge' them in. It must be regretfully admitted that the latter method is far too prevalent. It may be argued that 'fudging' is sometimes not only permissible, but even proper, just as draughtsmen, having accurately delineated the essential features of a mechanism, frequently draw a wavy line to cut off some non-essential, or mark its position with a simple cross. But the analogy is faulty; the drawing shows its limitations upon its face, but a 'fudged' record gives no indication that all portions are not equally trustworthy, and may lead to disastrous results when unexpected dependence is placed upon the untrustworthy portions. No engineer would think of placing a rotten plank across a winze in an unused portion of the mine in order to give a false appearance of completeness of safeguards. Yet this analogy with the fudging of records is more accurate than the one first cited. Records should be contemporaneous, they should be detailed, they should be complete, but first, last, and all the time, they must be trustworthy, and then there may be obtained from them definite information upon which reliance may be placed.

The Mining Industry and the Public Lands

By George Otis Smith

[*]The increasing share which the United States Geological Survey has been asked to take in the public land administration by the Interior Department has brought many of the problems connected with the public-land laws more directly to the attention of those charged with the work of the Survey. For over thirty years, however, these problems have interested the Survey geologists, who have had exceptional opportunities for first-hand observation in nearly all the important mining districts of the country, and for almost as long a period the engineers of the Survey have been in touch with the irrigation and power developments in the public-land States. This intimate experience with both field conditions and administrative problems justifies an expression of opinion which may be appropriate to this occasion.

The objects to be sought by amendment of the public-land laws are: first, purposeful and economical development of resources for which there is present demand, with retention of such control as may insure against unnecessary waste or excessive charges to the consumer, and second, the reservation of title in the people to all resources, the utilization of which is conjectural, or the need of which is at least not immediate. The means that are essential to the attainment of these objects are: first, the classification of public lands; second, the separation of surface and mineral rights; and third, the disposition of lands on terms that will secure the highest use, enforce development, and protect the public interest. Legislation based on these principles will not only secure the positive benefits of immediate utilization, but will also avoid the evils of speculative holdings of lands by fictitious use or by admitted non-use, for the future enjoyment of the unearned increment or of the profits of monopolization. With actual development made a condition of possession, and with land classification and separation of estates made preliminaries of disposition, the present-day utilization by individuals or corporations and the reservation to the people for future use become at once possible without conflict of interests.

The classification of the public land is essential to the administration of not only such laws as express the principle of separation, but also of those whose purpose is to promote the highest use of the land. Land classification is first of all the determination of the best use to which each particular portion of the public domain can be put, and by the organic act of March 3, 1879, this duty was specifically imposed upon the Director of the Geological Survey. Under the withdrawal act of June 25, 1910, classification is made possible in advance of disposition, and disposition can be postponed to await needed legislation.

The second step, both in principle and practice, appears to be that of making possible by legislation the separation of surface and mineral rights whenever the two estates have values which can be separately utilized. A notable advance in public-land legislation was the passage of the acts of March 3, 1909, and June 22, 1910, which provide that patents issued thereunder grant title to the surface of the land only, and thus permit agricultural development, while at the same time the United States retains title to the underlying coal deposits.

On the subject of water-power legislation the position of the Geological Survey is essentially that set forth in January of this year in a report addressed to the Secretaries of the Interior and of Agriculture by a joint committee representing the two Departments. The legislation there outlined would provide for lease of public and reserved lands of the United States valuable for water-power development for a fixed term, not to exceed 50 years, with moderate charges for use and occupancy of the land, and revocable only upon breach of conditions, or on account of the charge of excessive rates to consumers. These leases should be identical in terms, whatever the Department under which they are granted, with joint and uniform regulations governing all matters relating to water-power development of land belonging to the United States. Provision should also be made for periodic and equitable readjustment of charges, transfer of leases, preferential rights to renewal, and compensation for improvements at the termination of the leasehold. The law should specifically recognize water-power use as dominant, and both insure to the lessee undisturbed occupancy of the land needed for such use and reserve for future utilization all the land believed to possess value for water-power development; these lands to be designated by the President, but to be open to other entry subject to this reserved right wherever separation of the water-power use and other use is possible.

The chief advantage of land withdrawal and classification lies in the essential relation to the principle of proper disposition of the public domain, the real purpose of public-land administration being to secure such reservation or disposal of the people's land as will assure its highest use. The question of amendment of the present laws relating to the disposition of coal, oil, gas, and phosphate deposits on the public domain is recognized as fairly before the public by the specific mention of these minerals in the withdrawal act.

The coal-land law is unquestionably the most satisfactory of the present mineral-land laws in that it admits of the placing of an adequate valuation upon the deposits, and in the administration of this law the purpose is not only to base the appraisal price upon the quantity and quality of the coal present, and to give consideration to every known physical and commercial factor affecting the value of the deposits, but also to make the selling price approach as nearly as possible the present purchase of a royalty under a leasehold. Thereby it is intended to permit purchase for immediate development, and at the same time to prevent or at least discourage purchase for long-time investment or for monopolization. So many factors, however, require consideration that an ideal adjustment of the values is well-nigh unattainable for many if not for most coal lands, and on this account a strong argument may be made for support of the lease over the sale system. Under leasehold it would be comparatively easy so to adjust the relationship between ground rental and royalty as to prevent the acquisition of coal deposits until such time as their development should be profitable. On the other hand, it is possible, under the present law, and it is the policy in its administration, to readjust the prices from time to time, either by reduction to encourage development in special cases, or, more commonly, by raising the price on account of increased value due to new discoveries or to changed commercial conditions. Hardly less important, moreover, is the better control possible under a lease system, although against the advantage of such control must be weighed the cost of Federal management and the possibilities of inefficient administration or even maladministration. The present coal-land law, however, has one serious defect, which should be remedied if a leasing law is not enacted. The restriction of area that may legally be acquired to a maximum of 160 acres for an individual and 640 acres for an association is not in accord with good mining practice. The fixed charges on the cost of a modern coal mine, provided with the up-to-date equipment necessary to conserve life and property and to assure maximum recovery, are too high to be assessed against the tonnage of so limited a tract, especially if the coal seam is of moderate thickness. A law designed to promote the practical utilization of coal deposits, whether the system contemplates sale or lease, must provide for the holding of a large enough unit to permit the opening and equipment of a modern mine and to warrant its operation on an economical scale. Without such provision for commercial operation, too great an advantage is secured to the land-grant railroads and large coal companies already in possession of considerable areas of high-grade coal.

---

[*] An address delivered at the quarter-centennial of the Michigan College of Mines, August 9.

The present uncertainty whether the phosphate rock of the public land should be entered under the lode law or under the placer law is conclusive evidence of the need of legislation. As a matter of fact, neither of these laws is more applicable to the acquisition of beds of phosphate-bearing limestone than it would be to that of coal beds. The realization that the phosphate deposits are more extensive than was known or suspected when the Survey geologists began land-classification work in Idaho and Wyoming does not lessen, but rather increases, the urgency for a leasing law which will provide for the utilization of this large supply of mineral fertilizer, so as to meet both present and future needs.

The most urgent need of legislation for the disposition of mineral deposits is in the case of oil and gas. It is most apparent that the placer law, which is none too well adapted to meet modern conditions in mining placer gold, is wholly inadequate as a method of dealing with public oil lands, inasmuch as the discovery of oil is a late stage in the exploration and development of the land claimed under the law. Thus, large expenditures, extending over several months, if not years, are necessary before any right is acquired against the Government, and during all this time there is lacking any legal protection of the oil prospector against unscrupulous claimants or competitors better backed by capital. The need for remedial oil legislation is somewhat less acute than it was a year ago, by reason of the passage of the act approved March 2, 1911, the effect of which is to validate a class of claims which, while clouded by the construction which the Department was forced to place upon the misfit placer law, under which title to oil lands must now be made, were *bona fide* in that the inception of their development antedated the oil-land withdrawals. This enactment was in accord with the spirit of the withdrawal act, which provides for the protection of equities already established.

The need for a better law is, however, imperative, and the legislative action demanded by the situation should not be limited to an attempt to revamp the general placer law, but should be the enactment of an altogether new measure, especially adapted to provide for the sane and equitable development of this industry in the future. First, the new law should authorize the issue of exploratory permits, granting to individuals or associations the exclusive privilege of occupation, the sole condition of such a grant being diligent and adequate prosecution of development work, measured by the expenditure of fixed sums within certain periods, with possibly the payment of a small fee to the Government in lieu of such expenditure during the first six months. The issue of this permit should preferably be limited to one to each citizen or association of citizens, although after the lapse or surrender of such a permit the former holder should be allowed again to apply for an exploratory permit. In the second place, the law should provide that upon discovery, the holder of the permit be given a leasehold title with a royalty varied to meet local and actual conditions. The 'wildcatter', or prospector in unproved country, whether such unproved territory is classified on geological evidence as oil land or not, should be given special privilege to offset his greater risk. This privilege might take the form of an increased acreage, held both under permit and under lease, or a practical exemption from the payment of royalty, merely a nominal rental being charged under the lease. The chief advantage of the leasehold for oil over a fee-simple title lies in the prevention of monopolization through large holdings. Such large holdings without production would be guarded against by a ground rental sufficiently high to discourage the acquisition of lands except for immediate and continued development, although provision should also be made in the lease for surrender under terms which would protect the Government. This indirect control of development would be preferable to the direct enforcement, by forfeiture, of continuous production, which should be avoided because of the danger of disturbing the delicate equilibrium between supply and demand. Transfers of interest, under either permit or lease, should be permitted because of the absolute necessity in most instances of securing capital for both drilling and operating an oil well. The law, however, should set forth the purpose of such control of transfer, which would be to provide protection for the original locators, most of them men of small means, and more especially to secure the prohibition of too large holdings of Government leases by big companies.

Proposed amendments of the well established laws relating to metalliferous minerals always raise the warmest discussion. With the opinion of mining men in general favoring revision of the mining laws of the United States, and with commission after commission appointed by various bodies to suggest improvements, the statutes have remained practically unchanged for nearly forty years, while the geology of ore deposits and the technology of metal mining have made marvelous progress.

The law of the apex has proved more productive of expensive litigation than of economical mining. In many of the more recently established and more progressive mining districts this statute has been made inoperative by either common agreement or compromise between adjoining owners. Its repeal could not affect established equities under patents already granted, but would render possible more certain property rights in large mining districts as yet undiscovered, where new and valuable claims will be located 100 years from now. The unit of disposition should be the claim, preferably square, limited on its four sides by vertical planes, and of a size sufficient to allow the miner occupying two contiguous claims to follow the vein or lode to considerable depth, even if its dip is only 45°. Such definition of a mining claim is found practicable in both Mexico and British Columbia, and in the latter country the change from the apex law was effected without trouble or confusion.

The same knowledge of natural conditions that leads to the suggestion of a repeal of the law of apex forces the further suggestion that discovery of ore in place can not be made universally a prerequisite to the location of a mining claim. Geologic study of ore deposits has furnished examples in a number of regions where the present law can not be complied with, although rich deposits exist underground and their extent can be more definitely surmised than in most cases where ore is discovered at the surface. To meet such actual conditions the law should provide for the acquisition of metalliferous mineral land classified as such upon the basis of adequate geologic evidence, whether actual outcrops are present or not.

Most important, perhaps, in any amended mining law would be provision for enforced development, a principle expressed, it is true, in the present law, but not effective in its workings. A requirement of actual use as a condition of occupancy of mineral land can not be regarded as either novel or radical. As regards the large acreage of undeveloped land in many mining camps to which patent has already been issued, it is perhaps true that the situation is without relief, unless the Western Australia plan is adopted, whereby the Government steps in and permits mining under a lease, the proceeds of which are assessed, collected, and paid over to the owner. The principle invoked seems to be that no property owner can rightfully oppose the development of the State.

In the case of unpatented claims a remedy should be sought for what has been termed "the paralysis of mining districts", and the rigid requirement of annual assessment work should be made actual and effective by inspection and supervision, in order to put an end to the present procedure of allowing a claim to lie idle for practically two years after its location, not to mention the many localities where claims are held year after year with only perfunctory compliance, or even without any performance of assessment work—a type of local disregard for law that is in striking contrast to the observations accorded to the district customs and regulations of earlier days, whereby the right of possession was made absolutely dependent upon continuous operation.

The remedy, then, for the existing evil of idle mining property must be sought either in the adoption of leasehold, under which the Government can enforce operation, a system which fully attains the desired end of promoting mining development in Australia and New Zealand, according to the report made in 1907 by A. C. Veatch, geologist for this Survey, to the President, or in the thorough revision of the existing system. Radical amendment to the present law would be necessary in order to secure something more nearly approaching equality of opportunity. Some limitation should be put on the number of claims which an individual can locate in each mining district, and the prevention of monopolization would be furthered by the rigid enforcement of assessment development. The record of claims kept by a local official elected by the miners should be reported promptly to the nearest land office in order to furnish the Federal Government with a notice of the intention of the claimant, and thus to initiate the operation of effective inspection, the purpose of which would be to enforce the use and development of mineral land as contemplated in the law.

Whatever the details that may characterize this or that amendment to the public-land laws, the essentials to be sought are development of those resources for which there is present need and the protection of the other resources for which there is no immediate demand. To this end the lawmakers, in my opinion, should concern themselves more in retaining such control as will prevent either non-use on the one hand, or waste on the other, than in devising means of increasing the public land receipts by heavy royalties on the producing coal mine or hydro-electric plant. Tax the idle property instead. Through the full development of the mineral industry, the National can secure indirect benefits far in excess of any direct profits in the form of fees or royalties.

Cement Manufacture in Germany

By Otto Schott

*Many of the works situated in the north of Germany make their cement from the chalk on the coast and on the Baltic islands, and are forced to use at the same time a clay containing much sand and flint. They have, like most of the works in England, always given preference to the wet process. Chalk and clay contain naturally a high proportion of moisture and are so soft that they can be reduced to the requisite fineness without mills, simply by washing. In these factories the raw materials are washed very thin with about 80% of water, and, according to the arrangement of the plant, the stones and the coarse sand either settle to the bottom as the heavier constituents, or they are separated from the thin slurry by screens. The slurry runs from the washing basins into large settling basins, where it is allowed to settle. The water collecting on top is drawn off from time to time, and the sun and air help gradually to dry out the water remaining in the slurry until it becomes stiff enough to be dug out with a spade and pressed into bricks for the shaft or ring kilns, which are still used by most of the factories that work on the wet process. Some of these factories, however, have recently installed rotary kilns, and pump the slurry, containing 40 to 55% of water, direct from the settling basins into the kilns. It is often months before the slurry gets the consistence desired, and it is certainly a disadvantage of this wet process that so much time is lost before the product made months before can be actually turned into profit. Enormous sums are often represented by this half-finished product.

The wet process is considerably more advantageous, when pure chalk and clay are to be had, and it is not necessary to pay attention to eliminating impurities in the shape of quartz, sand, and flint. The addition of 40% water then suffices to grind the material in the wash-mills. This slurry is then simply run into the so-called mixing basins, where it is stirred up until the mixture is uniform. It is not necessary to thicken further this 40% slurry, and it can be pumped direct to the kilns. With these two ways of wet preparation it is presumed that the chalk and clay are naturally so soft that no special mills are necessary for grinding.

But it should especially interest producers in America that recently some works have started to prepare hard materials like limestone in the wet way by using special mills. This so-called thick slurry process has so far been introduced in Germany at seven factories, of which I inspected five during my last stay. Before I give you a full explanation of why, according to the opinion at present prevailing in Germany, thick slurry preparation is to be preferred to dry preparation, I should like to give you a short description of the working of a thick-slurry plant.

Such a plant is usually built in four stories, one above the other. The material comes from the pit to the top floor. The large pieces of limestone are here crushed to the size of a fist and fall directly onto the wet-kominutors placed below. The soft wet clay and marl are fed directly into this wet-kominutor, and roughly ground, with the addition of water. The rough slurry, which has 35 to 45% moisture, runs into the wet tube-mills, which are placed in the floor below under the wet-kominutors, and here it is ground quite fine. The factory has, according to its size, a number of large mixing basins, which lie below and in front of the wet tube-mills, and the slurry runs through pipes into these basins. A factory producing 1000 bbl. daily requires at least four mixing basins of 500 bbl. capacity each. As soon as a basin is three-quarters full, the mixture is made by testing the slurry every two hours and then grinding material either richer in clay or richer in lime and allowing it to run into the basin. The final adjustment can also be done by letting the slurry run from one basin into the other. The mixing basins are usually oval in shape; three stirrers run in each basin to keep the slurry in constant motion and mix it.

The slurry is then pumped by means of special pumps to small slurry bins over the kilns, and is burnt in the rotary kiln in exactly the same manner as dry material. The feed pipe to the kiln must be steep and wide, so that it does not choke. A difficulty with the burning is that the slurry is apt to roll together into large balls, which pass through the clinkering zone too quickly and do not get thoroughly burnt inside. These are called 'runaways.'

The kilns for the thick-slurry process have in Germany generally a length of 122 to 148 ft. and are 7 ft. 6 in. to 8 ft. 12 in. diameter. Only the kilns in the Dyckerhoff works are longer—150 ft. long and 9 ft. in diameter. Otherwise they are exactly the same as kilns for the dry process. The clinker is just as hard as the clinker made from dry material, and there is no difference in the further process of manufacture. Last year I often heard the view expressed in America that people in Germany were going over to the thick-slurry process quite generally. This is a mistake. As I have already told you, there are at the present time in Germany only seven such works, and in all of these special reasons led to the introduction of the thick-slurry process. Two of these works used the wet process from the beginning. At the moment only a single factory is altering its plant to the wet process, and from this you may see that the majority of the German cement makers still consider the dry process better, and in any case more economical. Only very special reasons, such as peculiarities of location or a naturally very wet raw material that could not be dried, have induced the German cement maker to introduce the thick-slurry process in a few places, although three engineering works are already making wet mills, and on this account are, of course, advocating the wet process.

---

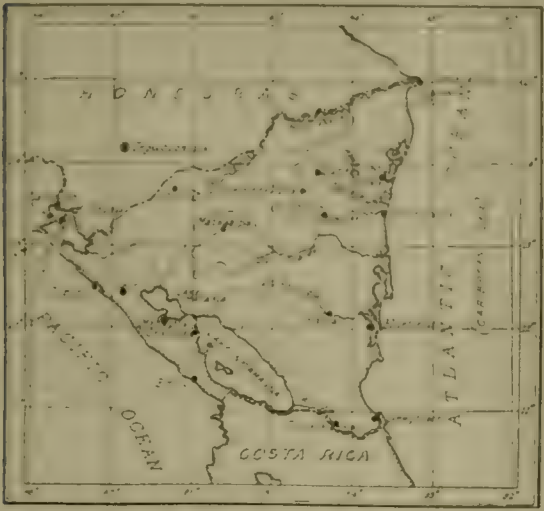
*A portion of a paper read before the Association of American Portland Cement Manufacturers, Kansas City, June 12 to 14, 1911.

Nicaragua and Its Gold Industry

By T. Lane Carter

We get enough of politics in the daily press, without introducing the subject into such a journal as this, but there is one political doctrine that mining engineers who lived in Nicaragua during the misrule of ex-President Zelaya thought of very often, the Monroe Doctrine. In writing of Nicaragua, this is the first point I wish to consider. My plea for bringing it in here is that mining depends to a great extent on sound political institutions, and that when you report on mining conditions in a country you must of necessity take note of the politics of the nation.

To the American at home the Monroe Doctrine is one of noble heritage. He joins in the cry, "America for the Americans. Let not Europe interfere or colonize in any part of Spanish America!" But the patriot is blind to the fact that the Monroe Doctrine carries solemn obligations, which we have failed in the past to recognize. Take the case of Venezuela, a country singularly blessed in mineral wealth. Who was responsible for such an anachronism as ex-President Castro? Indirectly, the United States. Under the Monroe Doctrine, Castro took liberties with Europe which should have brought fleets to his coast to chastise him. He realized that with the United States upholding this doctrine, he would be safe to disregard all international law. Because of men like Castro, the enormous wealth of Venezuela lies undeveloped, on account of the feeling of insecurity brought about by such lawless presidents.



MAP OF NICARAGUA.

Take the case of Nicaragua, equally as bad as that of Venezuela. Had it not been for the Monroe Doctrine, some European power would have protested to Mr. Zelaya so good and hard that the shock would have frightened him into being an honest man. But because of this doctrine, Zelaya carried on his rule of injustice for several years longer than he should, until the United States Government, at last stirred into action by the indignities shown her representative in that country by the dictator, as well as by other wrongs, moved to banish this man's evil influence from Central America.

The Monroe Doctrine is a good one, provided we realize the responsibilities it carries. If we will not allow Europe to call to order any tyrant in Central America who acts unjustly and hinders the expansion of the trade of the world, it is our obvious duty to keep order. What has been the fruit in the past of the doctrine of *laissez faire* on our part in Central America? Have the republics down there shown any more respect or consideration for our citizens than if we had pursued a firmer policy? It has been the experience of engineers that Americans abroad are not protected as are the citizens of Great Britain. I have known of cases where an American citizen has appealed to the British Consul in preference to the American representative, because he felt he would more readily get justice and protection by calling the British Consul to his aid. The foreign policy of the United States has been far too weak in looking after American citizens abroad.

With the advent of the Panama canal a new era seems to be dawning. The Panama canal has already justified itself, for it has awakened the United States to some realization of its duty in looking after the interests of its citizens engaged in the development of the mineral industry of Central America. Personally, I believe the future of mining in Nicaragua and the other republics was never brighter than at present. The history of Mexico will, no doubt, be repeated, and the five Central American republics will develop their great mineral wealth under more stable government, just as Mexico has, under stable government become one of the leading mining regions of the world. With the opening of the Panama canal the necessity for peace will become greater, and if our Government continues to show firmness, revolutions in Nicaragua and elsewhere will cease.

TRAVEL IN NICARAGUA.

The trouble in these countries is not with the people, but with a coterie of disreputable politicians and soldiers of fortune from the United States and elsewhere who, by a system of tyranny and oppression, exasperate the people beyond endurance and force them to rebel or starve. I was in the revolution against Zelaya in Nicaragua, and I know that for months the people of the country endured oppression as great as that imposed upon the peasants of Russia.

The political situation in Nicaragua is now promising for mining. Estrada, the new president, is a man who knows the importance of mining to his country, and he is anxious to give foreigners fair treatment and to welcome them and their enterprises. A large loan will be negotiated, and a program of railroad construction undertaken. It is most important to have railroad connections between the Atlantic and Pacific coasts. At the present time the only railroad in the country is in eastern Nicaragua from Corinto to Managua. To go across Nicaragua is a trying trip, for there are no roads, only paths through the forest, and the traveler must either walk or go on muleback.

Mining has not played as important a part in the history of Nicaragua as in some parts of Spanish America—Colombia and Mexico, for instance. Columbus sailed along the east coast of Nicaragua on his second voyage and landed at Cape Gracias a Dios. The Spanish adventurers found gold in the country, in western Nicaragua. The low, swampy coast-line of the Atlantic side of the country did not attract them, and this section of Nicaragua remained unknown until recent years. As a matter of fact, there are in the world few countries more sparsely settled than Nicaragua. A real 'boost' to mining in Nicaragua was given in the days of the gold excitement of California. Many of the fortune-seekers traveled to that Eldorado through Nicaragua. The chances of gold mining seemed so inviting that many miners stayed in Nicaragua and went to work. La Libertad district, in the State of Chontales, benefited by this invasion, and the production of gold started then has never entirely ceased.

There is very little literature bearing on the subject of the history of mining in Nicaragua. William Walker, that prince of soldiers of fortune, in his book, 'The War in Nicaragua', published in 1858, has very little to say about mining. His business was fighting, and he had no time to notice the gold industry. In a delightful book, now out of print, 'The Naturalist in Nicaragua', Thomas Belt not only describes the flora and fauna, but the mines as well. He was in charge of a mine owned by an English company in the La Libertad district, and complains of the difficulty he had in making a profit from ore running $7 per ton, with a milling capacity of 2000 tons per month. Mr. Belt states that the whole cost of treatment, including all charge for mining, carriage, reduction, amalgamation, and management was about $2 per ton, so that we see that as long ago as 1869, when this work was done, Nicaragua had remarkably low working costs. The cyanide process was unknown then. If it had been known, the manager of the mines would have made larger profit. As it is, he was evidently competent, for he mentions that after catching the gold with mercury, the sand and water then passed over inclined tables covered with blankets, the fibres of which intercept particles of gold and mercury that have escaped from the first process, and afterward into a concentrating-box, where the coarsest grains of sand and the sulphides of iron, copper, and silver were caught and, with the sand from the blankets, re-treated in arrastres.

Mining in eastern Nicaragua did not commence until 1888. There was an old German who lived for five years on the Principulca river trading with the natives, who had such influence with the Indians that they would bring him pieces of rock carrying free gold. Most of the mines found have been due to the clues given by the Indians, which later were followed up by the prospectors. Placer mining has never amounted to much in eastern Nicaragua, nor has a successful dredge ever been erected. Attention has been directed to vein mining, and it is this branch of the industry on which the future development of the country rests.

One of the first mines to commence operations was the Siempre Viva, on which Courtenay De Kalb made a report as long ago as 1892. This mine has produced steadily for years and still keeps at work. Later on, and also in the Pis Pis district, such mines as the Lone Star, Bonanza, Constantia, and Concordia, were opened on a small scale. Today the most important mine in the district is the Bonanza. A few years later La Luz y Los Angeles mine, in a district some 35 or 40 miles south of Pis Pis, was sold to an American company. This mine is still in active operation. The Topaz mine, in the Rama district, up the river from Bluefields, has been turning out gold for years. No attention was given to the tailing from the mills at first, simple amalgamation being the only method used. Cyanide plants were erected at the mines. One more step is necessary; the putting in of slime-plants.

Ask the average man and he will tell you that Nicaragua is one of the most unhealthy countries in the world, a land where one man out of two dies of yellow fever or malaria. It will take a long time to eradicate the impressions made by the high death rate during the digging of the Panama canal by the French. The assertion has been made that for every cross-tie laid on the railroad, a man died. People have thought for years that this high mortality was typical of all Central America.

Take it on the whole, Nicaragua is not an unhealthy country. After the experience of the United States Government at Panama, the world knows what can be done in making the tropics habitable. It is astonishing to find that the death rate in the Canal Zone is now as low as in many American cities. Most of the sickness in Nicaragua is found in the flat, marshy land along the coast and the rivers. When you get into the highlands and away from the mosquitoes, you escape from malarial fever. Much of the illness of the past has been due to hardships and neglect. Improper food and too much whiskey have had as much to do in wrecking health as the mosquitoes. No cases of yellow fever are on record as having occurred in eastern Nicaragua. The yellow fever mosquito (*Stegomyia*) is occasionally seen along the rivers, but as it has not been inoculated it is harmless.

The only enemy that the mining engineer going to the wilds of Nicaragua need fear is malaria. Fortunately, the type of malaria prevalent in Nicaragua is not as malignant as in other parts of the world, and the engineer gets rid of the malady when he goes to temperate climes. The sole cause of malaria is the mosquito. Remove it and the disease ceases. The engineer in Nicaragua should expose himself as little as possible to these insects. He should always sleep under a net. When he makes a permanent camp, the forest should be cleared away to let in the sunlight. Before going to the tropics, the engineer should read up on the subject of malaria. This knowledge will help him to prevent attacks, and to take care of himself if the disease lays him low. If he is in good health when he visits Nicaragua, the chances are that even in the swampy districts he will go for nearly a year without any attack. Many people escape, and if they live in the hills and mountains, may remain in Nicaragua for years without a day's sickness.

I wish the mining laws of the United States were as admirable as those of Nicaragua. The framers of the law had the poor man in view when they made it, for there are few codes which give the man without means a better chance than the mining laws of Nicaragua. Taxes are light, and the holder of a claim is not forced, as in the Western States, to do $100 of assessment work per claim each year. The size of a claim is 14,184 sq. yd., on which $2 per year in taxes must be paid. The law demands prompt payment of the taxes, which must be settled by the first of February. If not paid, the property is sold at auction.

The mining law is liberal in its granting of sites for establishing the plant where necessary for the treatment of ores, and also for water rights. For a mill-site of 100 hectares the law requires only 80c. per hectare per annum. As the dip of a vein varies, so does the shape of the claim. The width of the claim is determined by the dip, according to the following table:

From 30°	up to 45°	200 metres.
" 45°	" 50°	165 "
" 50°	" 60°	135 "
" 60°	" 65°	115 "
" 65°	" 90°	100 "

Every facility is granted in the acquiring of titles. The judge of the district appoints a competent man to measure the claims, the owner, of course, paying all the fees for surveying, stamps, and so forth. The owners are compelled to keep in order the monuments on their claims, and also to keep clean the boundary lines of the claims. There are one or two important reforms to be made in the Nicaraguan mining law. The most important is to make it possible for a large corporation to make sure of the 'deep level' claims of their property.

In the older sections of Nicaragua, around the capital, Managua, and the larger cities, the roads are passable, but in eastern Nicaragua there is not a road. To transport material overland is very expensive and difficult. Every effort is made to reduce to a minimum the distance on land, by working up the rivers and creeks with the freight to a point as close as possible to the mine. The freight is carried from the landing station, on the river to the mine, with mules or oxen. Through the vast, thick forest a trail is made by the natives with their long knives or *machetes*. The pack-animals follow this trail with their burdens. As the soil is soft and moist, it does not take long for the hoofs of the beasts to wear holes from 18 to 24 in. deep along the highway. This makes a difficult road to traverse, even in the dry season, but in the wet season the paths in the Nicaraguan forests are sloughs of despond. No wonder it costs from 5 to 8c. per pound to transport the freight from the river to the mine. Heavy pieces of machinery are dragged to the mines with oxen, use being made of block and tackle.

On the larger rivers, as the Escondido and the Wanks, steam paddle boats are used, but on the rivers where there are numerous waterfalls and rapids, all the freight is paddled up the streams to their destination in canoes or *pit pans* by the Indians. The difficulties of transportation have prevented the development of the mineral resources of the country as much as anything else. One of the first things that should be done is to open up the country with railroads.

There is a fine field in Nicaragua for geological investigations. This is not the place for a detailed dissertation on the structural geology of Central America. During the glacial period, it is maintained that the average sea level was 1000 ft. lower than it is today, and a variety of reasons have been urged for this difference in level. In early Pleistocene time it is probable that the coast of Nicaragua went far out into the sea. The islands of the West Indies, Porto Rico, the Virgins, the Anguilla group, Cuba, the Bahamas, and Hayti, once formed continuous dry land, and obtained its land molluscs from Central America and Mexico. The engineer is more concerned about the economic aspect of the geology of the country. He finds a great variety of vein structure and formation. Apparently the main mineral wealth of Nicaragua is gold. Up to the present, of the 500 mines registered in the republic, 490 are gold mines or prospects.

The majority of the formations are igneous. Occasionally small areas of crystalline limestone are found, as well as schists. Around Lake Nicaragua the signs of vulcanism are apparent, but in eastern Nicaragua and Honduras the formations are regular, and are seldom disturbed by faults or dikes. In the Pis Pis the well defined veins on which the Bonanza, Lone Star, Siempre Viva, etc., are located, extend for many miles without any large breaks. It is impressive to see the 50-ft. veins, worked by open-cut, on the Bonanza mine, and to notice that along the outcrop there are no faults or dikes. The country rock in the Pis Pis district is porphyry. As a rule, the veins are replacements in porphyry with a well defined foot-wall, and in many cases a well defined hanging wall. The vein filling is usually a quartz with sulphides of the common metals. There are many 'horses' in the veins. The water action has been intense, and as a rule the vadose zone does not extend more than 200 ft. The denudation of the veins has been enormous, and this has formed along the slopes of the hills a layer of soil from 3 to 20 ft. thick, locally called *manto*, which carries gold. At times this *manto* has been concentrated to such an extent that it is of high enough grade to mill. There are places in it here and there of great richness, but as a general thing the *manto* is very erratic.

The vital question, 'What will happen to the veins in depth?' has not yet been solved, as practically all the mines in eastern Nicaragua are worked through adit-levels. The indications are that when the permanent water-level is met the character of the veins will change rapidly. The possibility of this fact should be taken into account in the designing of any metallurgical plants. That the veins will extend to great depths is probable, but whether the gold content will persist remains to be proved. The width of the veins in the Pis Pis district is great, and up to the present no one has worried about what will happen at a depth of a few hundred feet, as there is sufficient ore above the water-level to keep the small mills running for many years.

Of course, there are veins in Nicaragua that are narrow and very rich, but I believe that the mainstay of the country will be the big medium-grade veins. I saw a curious gold vein in the Oconguas district, a tiny stringer with free gold in a limestone. One frequently finds veinlets in limestone in Nicaragua containing free gold, but they are more erratic. Fig. 1 is a sketch of a vein in limestone in the Oconguas district. An interesting geological formation is seen at the Santa Rita mine. This is illustrated in Fig. 2. The porphyry has been shattered and is full of veinlets running in all directions. The denudation has been so great that the oxidized zone does not extend far into the hill. The rock in the oxidized zone is of low specific gravity. Some of it will float in water like pumice stone. It is probable that many such formations as that at the Santa Rita mine will be found when the country is better prospected.

There are few countries in the world more difficult for the prospector than Nicaragua. The man who has looked for gold in open countries like Nevada and the Transvaal, finds, when he first goes into a tropical country like Nicaragua, the impenetrable forest, the thick covering of soil and sub-soil which hides the formation, and the difficulties of transportation, confronting him. But he soon learns by experience the methods to use in looking for gold. Fortunately, there are many streams in the country, and these cut the formations at frequent intervals, giving the prospector a good chance to study the rock. The keen eyes of the Indians and the Nicaraguans are far more likely to find gold than Europeans, and as a rule the white man takes one or two of the natives with him when he goes into the forest. The prospector who goes to Nicaragua should either be 'grubstaked' or have some money of his own. Being a new country, it is not a cheap one in which to prospect. One thing the new convert must beware of, and that is the fact that the gold is rather light and contains a large amount of silver. He is very liable to overestimate the gold in panning. As a great deal of the gold is 'bound', he should frequently have assays made of material which he considers gold-bearing.

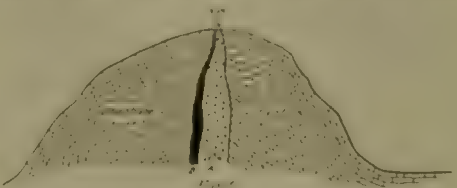


Fig 1

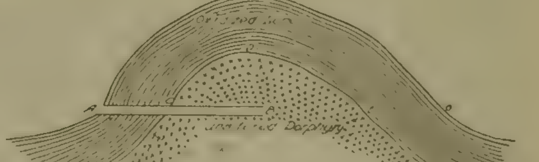

Fig 2

All of the mines that have been started have relied for awhile on wood for fuel, but they soon found that this is most expensive. While the land in Nicaragua is covered with forests, the number of trees used for timber and fuel is small. Most of the bushes are worthless. Fortunately, the country is blest with an abundance of water-power, and the mines soon get their power either direct from Pelton wheels or by hydro-electric methods. For a month in the dry season streams run low and there is frequently a scarcity of power, but in the wet season there is an abundance. A large company operating in Nicaragua would probably desire to provide for this one month of dry weather by putting in an auxiliary steam-plant. If this is done, and the mines are well served with railroad facilities from the coast, it will probably pay to bring in coal from Alabama.

Nicaragua is better off as regards labor than other countries, such as British Columbia and Alaska. Labor in Nicaragua can be divided into four classes. The Indian, the Spaniard or Nicaraguan, the Jamaican, and the European.

The Indians are expert in their canoes, and all the transportation on the rivers is in their hands. As hunters they also do very well. In opening up a new district it is possible to supply 25 to 30 men constantly with fresh meat if a hunter is employed to go out after the game. The Indians do not do well as miners or artisans. They receive from 40 to 80 cents per day and their board.

The Spaniards or Nicaraguans are the miners of the country. On the whole, they are better workers than the peons of Mexico and work best when put on contract. While on day's pay, they earn from 80c. to $1 per day, United States currency. When on contract they do surprisingly good work at times and earn from $3 to $4 per day. Most of the Spaniards come from the interior of the country and from Honduras. It is important for any large mining corporation that starts work to lay out a town for the employees, so that they can bring their families from the far more populous interior and settle permanently near the mine. The Jamaicans, or negroes, seldom work in the mine. They are employed as mechanics, carpenters, and the like. They are not popular in Nicaragua, being insolent and lazy. You will take them for British subjects, but if you ask the Jamaican in Nicaragua, he draws himself up with pride, and exclaims, "I'se a British object, sah." It is the best policy to divide the labor on the mines so as to have an equal number of Indians, Nicaraguans, and Jamaicans. The feeding of these people is expensive, on account of the excessive freight rate charged on imported foodstuffs. Most mines endeavor to raise fruit and vegetables with which to feed their men in order to reduce to a minimum the material brought to the mines. It costs from 60 to 90c. United States currency per day per man to feed this labor.

There is no more demand for Europeans as laborers in Nicaragua than in Mexico. The few that are found on the mines are in charge of the native laborers. You will seldom find a white man working as a miner. The best chance for the European in Nicaragua is to go to work on his own account, either prospecting or similar work. This, of course, requires a little capital. For the mechanic to go there with simply his muscles and no cash, the chance is distinctly a poor one.

The methods of mining employed on some of the properties have been distinctly primitive. On some of the small veins, from 3 to 6 ft. wide, there has been a great deal of gophering, not as much as one would find in the *antiguas* in Mexico, but sufficient to honeycomb the vein. In the narrow veins the ore is stoped out from the adit-level by back stoping or overhand stoping. The rather soft hanging wall is kept up by timbers. The dip of the veins is from 60° upward.

On the large veins the work is carried out on the open-cut system. At the Lone Star mine, however, during the rainy season, when it is almost impossible to mine in the open, the ore is drawn from underground stopes. The vein in the stope varies from 15 to 40 ft. The vein material is somewhat harder than the country rock. For this reason no attempt is made to support the hanging, but it is caved. An attempt is made in Fig. 3 to show the method employed in stoping underground at the Lone Star. Raises are put up every 50 ft., as at 1, 2, 3, 4. When the ore is blocked out in this manner, stoping commences at the top, as at *CD*. The ore is handled in wheelbarrows along *CD* and *EF* and dumped down the chute 1 or 2. Where the vein is stoped up to the hanging wall it is generally found that the pressure of the caved material above is sufficient to bring down the hanging. If not, a hole is placed in the hanging and it is caved. By this method it is possible on the Lone Star to extract all the ore from the stope without using much timbering.

The engineer is surprised to find such low working costs in a country like Nicaragua. The total cost at the mines with large veins, including mining and development, milling and cyaniding, etc., runs from $2.50 to $3 per ton, crushed. The reasons for these low working costs in spite of the high cost of transportation, are obvious. In the first place, power is cheap. On no mine in the world can one find a more ideal power scheme than the one on the Lone Star, where the mill and all the machinery is driven direct by water-power. The hydro-electric possibilities on a mine like the Siempre Viva, mean cheap power for all the properties in the district.

The veins, as a rule, are wide, the ore is easily stoped, labor, while not plentiful, is fairly efficient; so the labor costs are not high; and these points, of course, make for low working-costs.

The ore is rather soft, and the cost of milling, therefore, is moderate. The consumption of cyanide, per ton crushed, is normal. When it is realized that the present low working-cost in Nicaragua is obtained on plants with a daily capacity of 100 tons and less, one sees the great opportunity for very low costs in this county were the mines served with railroads and milling plants of a larger daily capacity. The use of rock-drills for stoping and development work will probably replace much of the hand work now done in the mines. This also will make for low costs.

The value of the ore in the different mines varies considerably. A conservative figure would be about $6 per ton for the large veins in the Pis Pis district. There is no reason why, with the proper equipment, there should not be an extraction of 85 to 90% of the gold content. This would give a recovery value of about $5 per ton, and a profit, with a modern plant, of about $2.50 per ton.

The metallurgy of gold in Nicaragua has been decidedly unsatisfactory. It is not a 'free-milling' country, and for years on some properties the extraction of the gold by plate amalgamation was from 33 to 45%. The introduction of the cyanide process was a great advance, but, unfortunately, only the sand has been successfully treated and not the slime. At one property, the Bonanza mine, the slime is treated by an entirely unsatisfactory method, the decantation process. It is questionable whether this process should be used anywhere. It is certainly a most unsightly misfit in Nicaragua.

While the slime problem presents some difficulties, on account of the large amount of alumina present, I am sure that the slime problem in Nicaragua can be solved. Laboratory experiments gave me an extraction as high as 90%. The only serious trouble was in clarifying the gold-bearing solution. The value of the slime is about equal to that of the sand, running about $2 per ton, and amounting in quantity to 50% of the tonnage crushed.

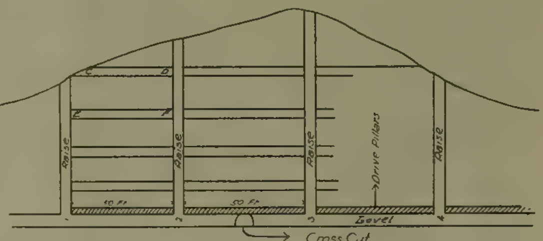

FIG. 3.

On the whole, it will be found that such machinery as the Huntington mills will be more suitable at the present time in eastern Nicaragua than gravity stamps. Where these muddy ores are crushed with stamps the efficiency is low, as the material sticks to the shoes and dies, increasing the weight of the stamps, simply augmenting the trouble. To my mind the best method of crushing the typical Nicaraguan ore is to pass it through crushers, then rolls, and then through the Huntington mills. As the ore is rather porous, there is no necessity for fine grinding, so that tube-mills will not be required in Nicaragua. I have obtained an excellent extraction by crushing with a 20-mesh screen.

The scheme of crushing in a cyanide solution and doing away with all amalgamation should be carefully considered, especially in the Pis Pis district, where the ores are amenable to the cyanide process. The fact that the amount of gold recovered in the Pis Pis district never equaled more than 50%, and is often as low as 15% of the gold in the ore, goes to show the importance of direct cyanidation in the treatment of these ores. The consumption of cyanide varies from ½ to 1 lb when treating the ores in the oxidized zone. Occasionally bunches of sulphides of lead and zinc are found, and if these pieces get into the mill the consumption of cyanide is increased. As these sulphides are not, as a rule, high in gold, it is profitable to sort these out before the ore goes to the mill.

Ordinary cone separators are used to divide the sand from the slime. It is of great importance to make a complete separation if a satisfactory extraction of the gold is desired. In one case that came to my knowledge, the people ran the whole product from the mill into the sand tanks. The amount of gold obtained from treating the mill pulp by this method was, of course, insignificant. A man who knew his business came along, made a careful separation of the sand from the slime, and had no trouble in obtaining an extraction of 88% of the sand.

The question of treatment tanks is a very important one. As a rule, they are built of wood imported from Louisiana or California. At the La Luz mine they have erected steel tanks at a great expense. Provided the property will last for a number of years, steel has the advantage of durability. With such splendid woods as are obtained in Nicaragua, one would think that the tanks would have been constructed from the native wood. This has not been done in the past on account of the absence of sawmills, but in the future, especially in new districts, it is probable that the tanks will be built from the wood of the country.

On account of the high cost of transportation, it is impracticable to use lime as a neutralizer. The vast coral reefs along the coast will give a cheap and abundant supply of lime in the future when railroads are constructed. At present caustic soda is used in the cyanide plants. The strength of the solution varies from 0.2 to 0.3%. Occasionally a little trouble is experienced with arsenic, but T. W. Bouchelle, the chemist at the Lone Star mine, overcame this difficulty, when he noticed a deposition of arsenic on the zinc shaving, by heating up the solution in the boxes with live steam. The heat caused the arsenic to scale off of the zinc and settle at the bottom of the boxes. Now and then bunches of copper are found, and these are likely to cause trouble if the cyanider does not understand how to treat the problem. By the use of bichloride of mercury in the boxes, the trouble from copper can be averted.

Sulphuric acid is used in the clean-up. The transportation of acid in a tropical country like Nicaragua is a difficult and expensive feat. The gold-bearing material from the clean-up, however, is so base, that to get the gold out without the use of sulphuric acid is a serious problem. The assay offices of Nicaragua are equipped to take care of the routine work. The gasoline furnaces, such as the Braun, have been a boon to the country, and it is possible to make a gold assay in these furnaces in the wilderness for 10 cents an assay and less. On account of the heavy rainfall, which varies from 125 in. per annum in the Pis Pis district to 300 in. at Greytown on the coast, the damage done to balances and survey instruments by excessive moisture is considerable. Assay textbooks, etc., rapidly deteriorate through mildew and must be kept wrapped in cloth if they are to be preserved for a number of years.

To give an adequate description of Nicaragua and its gold industry would take far more space than I have at my command. I have tried to give briefly some of the salient facts in the mining industry of this republic, which is so old that it can be considered new. Better days seem to be in store for this country. Not only American engineers, but the American people wish the country well. We all hope that under the guidance of the new president, Estrada, the night of tyranny which has for so many years hung over this beautiful land like a pall, will give way to the day of liberty and prosperity. In the past the indiscriminate granting of concessions has done a great deal to hold back the development of the country. The present Government has abrogated these concessions, and the country will now be thrown open to the prospector.

There are many difficulties in the way of the mineral industry of Nicaragua, and the development of the country will probably be slow. The owners of mines and prospects in the Republic do not fully realize these difficulties, and the prices frequently asked for half proved properties are absurd. They should remember that other countries besides Nicaragua are calling for funds, and that in this competition for capital the money will go to the industry offering the most attractive terms.

A NICARAGUAN MINE.

San Francisco Meeting of the American Institute of Mining Engineers

As already announced, the one-hundred and first meeting of the Institute will be held in San Francisco, California, beginning Thursday, October 19, 1911. The last meeting of the Institute in California, September, 1899, was so eminently successful, due to the careful arrangements made by the local committee for the comfort and enjoyment of the party, that it is regarded as having established a standard of highest merit. The description of the many interesting places visited, and the cordial hospitality showered on the party throughout the trip, are recorded in the *Transactions* (Vol. XXIX), and in a special volume on *California Mines and Minerals*, 450 pages, published by the California Miners' Association under the direction of E. H. Benjamin, secretary, who is the present chairman of the Committee on Excursions of the coming meeting.

The chairmen of the various local committees in San Francisco are: Executive, W. C. Ralston; Sessions, F. W. Bradley; Excursions, E. H. Benjamin; Reception, S. B. Christy; Finance, M. L. Requa; Press, H. F. Bain. The Institute headquarters will be established at the St. Francis Hotel. The local program, controlled by the Local Committee, provides for the opening session at the St. Francis Hotel, in San Francisco, Tuesday afternoon, October 10, to be followed by other sessions on Wednesday and Thursday mornings. On Thursday afternoon, October 12, a special train of Pullman and dining cars, in charge of the Local Committee on Excursions (E. H. Benjamin, chairman), will take the party to Bakersfield, arriving early Friday morning for a visit to the various oilfields. On Friday evening, October 13, the party will proceed by train to the heart of the gold-dredging district, near Folsom, spending Saturday morning, October 14, in visits to the gold dredges and the great rock-crushing plant of the Natomas Con. Company.

On Saturday afternoon, through the courtesy of Hiram Johnson, Governor of California, a public reception will be held in the State Capitol, Sacramento. Later in the evening, the train will transport the party through the

Napa and Sonoma valleys, arriving at the Bohemian Club Amphitheatre on Sunday morning, October 15, where a barbecue luncheon will be held. The day will be spent in this delightful grove and an orchestral concert will be given on the great natural stage, where the plays of this famous club are presented. On Sunday evening the party will return to San Francisco, and devote Monday, October 16, to rest and preparation for the departure of the Japanese delegation, and possibly to a few local excursions. On Tuesday morning, October 17, the return trip will start for Chicago.

Who Pays For It?

By Herbert C. Enos

While recently visiting a small mine in the State of Guerrero, Mexico, I noticed that the track from the mouth of the tunnel to the end of the dump, a distance of about 250 feet, was poorly laid, with a grade of about 2% in favor of the returning empty car, so that two men were required to tram the loaded car from the tunnel mouth to the dumping point. I inquired of the manager why he did not lower the dump end of the track enough so as to have a ½% grade in favor of the loaded car, and received this answer: "Well, it does not make much difference, since the trammers are on contract."

I have received that same answer many times in Mexico with reference to contract work about mines. Ignorant or shiftless superintendents expect Mexicans to make all sorts of break-neck efforts for the simple reason that they can get the job done comparatively cheaply on contract. Because you can get a Mexican contractor to hire boys to pack waste up ten flights of ladders with the stuff in baskets *(chiquihuites)* is no reason why you should not put in a windlass and pay the miner less money for his contract, thereby paying for the cost of the windlass and putting money in the company's treasury besides.

I have reduced the contract price on driving in limestone with machines from $28 to $26 per metre by simply giving the contractor an iron plate to shovel on and seeing that the track was kept close up to the working face. This particular drift to which I refer was to be driven a distance of 300 metres, so with a saving of $2 per metre, we have $600 saved against $20 invested in an iron plate.

I could cite a great many similar cases, and they all show that if a contractor has difficult conditions to work under, he is not the loser, as the company pays for it. The Mexican contractor generally expects to make about 25% more when working on contract than he does when working for daily wage; hence if conditions are made so that it is easy for him to work, he will accept the contract at a lower price than he would under poorer conditions.

Good chutes in which the ore does not block, track laid with a fixed grade using 16-lb. rails, and cars of a proper design, all help the contractor to deliver more cars to the station, and therefore he can afford to accept the contract at a lower price than if conditions were bad, thus reducing the working costs of the mine. With a piece of paper and pencil, and the use of a little simple arithmetic, these things can be figured out and the company saved much money.

Another point which seems to me to be an excellent one, but which I have never seen so rigorously enforced as is done at the El Oro mine, operated by the El Oro Mining & Railway Co., is the punishment of men by a fine or some other means, who do not remain in the stopes, or who sleep when they are supposed to be working, or do other things which take them from their work. This applies to men who have contracts as well as to those on day wages. A good many managers contend that when a man has a contract he has a right to work, loaf, sleep, or do as he pleases. In the United States that may be all right, but the Mexican miner is a great conversationalist and 'josher', and likes to sit around the mine in the morning in groups and talk it over. I have been in large mines in the Pachuca district, where men who went into the mine at 7 a.m. did not commence to hit the drill until 9 or 10 a.m. The result can best be shown by an example.

Take, for instance, a mine working 1000 men with 10-hour shifts, where the men are obliged to get to their respective working faces as soon as they enter the mine. It is a rule of the company, and applies to contractors as well as to men earning day wages. Generally a contract is let for the week or *quincena*, fifteen days, and the average contractor generally comes out with about 25% more money than he would earn working for day's wages; of course, sometimes a good deal better and at others considerably less, with about 25% for an average. In this mine the men get to work at once, and in the 10-hour shift they probably work nine hours.

Now suppose this company changes management and the miners are allowed to sit around for an hour in the morning discussing the political situation in Mexico, and are allowed to go wandering about the levels when they feel like it—and they get that feeling about three or four times a day—they average about six hours at work instead of eight or nine, with the following result. The contractors begin to come out poorly and in many cases do not make day wages. Then, of course, they object, and it becomes hard to let the old contracts at the same prices; perhaps the shift boss will think that they are not getting quite enough, and he will gradually raise the price of the contracts a little, and he may be forced to raise some of them until at the end of six months the price paid for contracts will have risen 20% or more and the men receive as much for working six hours a day as they formerly did for working eight or nine hours. In other words, the company again pays for it.

Along this same line is the question of working nights in Mexico. The El Oro company has stopped all night work where possible, with excellent results. I had the good luck to be at one of the company's mines in Chihuahua during the cutting down of the night work. I found that when working men on the contract system, by adding five men to the day force you could dispense with ten of the men on night shift. On the daily wage system, one man on the day shift will, on the average, do more work than three on the night shift. It may not be possible or advantageous to cut out night work on some properties, but there are many mines in Mexico where the night force could be cut down considerably, or dispensed with altogether, with profitable results.

The average Mexican miner will not sleep in the daytime. He visits around and spends the day in the *cantinas* or saloons. Animal instinct impels animals to seek their rest at dusk, and the Mexican miner has not, up to date, lost any of his atavism. Mexican contractors will accept contracts at lower prices when they do not have to put on a night shift. This is especially true of ore contracts, and companies should take advantage of the fact where possible, and get away from the idea that because it is a mine they have to work both day and night.

Copper Exports and Foreign Surplus

Exports of copper as compiled by the New York Metal Exchange and the foreign visible supply on the first of each month are noted below, all figures being in tons.

	Exports.		Visible surplus.

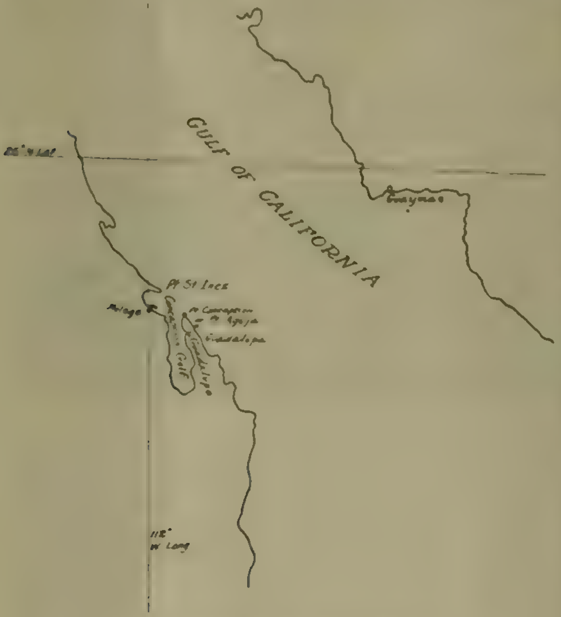
Manganese in Lower California

By H. Vincent Wallace

The area embraced in the following description was visited during the month of December 1910, and lies in the municipality of Mulegé, South District, Baja California. The town of Mulegé has a population of about 1200 people, and is situated in Long. 111° 58′ W., Lat. 26° 53′ N., and about 95 miles W.S.W. from the port of Guaymas, in Sonora. Mulegé is beautifully situated on a river of the same name, about three miles from its mouth. The river rises about a mile to a mile and a half above the town, in a large *cienega*, or group of springs, which also serve to irrigate a large tract of very fertile land, devoted to market gardening, olive culture, and magnificent groves of date palms. Practically all this industry is in the hands of Chinese, who by their energy have developed a large export trade. Dried dates are consumed in large quantities by all the inhabitants of the locality, and it is almost a staple diet of the fishermen, sailors, pearl divers, and others.

Another industry of local importance is the salt refining, which is carried on at the mouth of the river, where, owing to the rise and fall of the tide, which amounts to eight feet, sea water is admitted as desired into a series of basins which have been dug in the lowest portion of a small peninsula or neck of land, just on the landward side of the harbor entrance, and back of the custom house. The collected salt water is allowed to evaporate slowly, and the impure salt crystals are collected and sacked. The resulting product consists of sodium chloride with a good deal of magnesium chloride. This is sold to outgoing ships, and, although bitter, is used along the coast for pickling fish. If scientifically conducted, a much purer salt could be produced at a very low cost by taking advantage of the different stages of crystallization of the various salts. The local method of pickling olives consists in merely placing the olives in a hot crude salt brine, which, owing to the magnesium content, gives a very bitter flavor. There appear to be no attempts at olive-oil manufacture, and as there are large numbers of sardines in the estuary and outer bay, at certain seasons, it would seem that there is a good opening for a cannery at this point.



MAP SHOWING MANGANESE DEPOSITS.

About a mile from the north of the river there is a large body of kaolin which is worthy of exploitation. It is of fair quality, even on the surface, and by systematic development would probably afford a substantial revenue. The exposure on the beach is impure, due to a slight iron content, but this is probably due to a local concentration and levigation tests could be made with a view to determining how good a product could be obtained by simple means. Samples of this material, both washed and unwashed, should be submitted to pottery and tile works in San Francisco, Seattle, Portland, and Los Angeles, as I understand that a few selected lots submitted to one firm in the last named city met with approval. Probably it is only a question of cheap mining and adequate loading facilities, with a maintenance of grade, to develop an important industry.

KAOLIN DEPOSIT NEAR MULEGÉ, BAJA CALIFORNIA.

Justice would hardly be done to this portion of the Gulf of California, if mention were not made of the pearl-fishing industry, as it is a well known fact that some of the finest black pearls in the world have been sent from Mulegé. Owing to the fact that this business has been largely monopolized by some companies which have obtained concessions from the Government, the pearl fishers are not as actively employed as formerly, and only a few divers are working on their own account, carrying on a more or less illicit traffic. Merchants complain that since the granting of the concessions the pearl-shell business has likewise dropped off to almost nothing.

The manganese deposits are all situated on the peninsula, Point Concepcion, which terminates at its northern extremity in Punta Aguja. This neck of land encloses the Gulf of Concepcion, which has a north-northwest direction, and the point of the headland is approximately 14 miles across the bay from Mulegé. One of the deposits, and the one of least importance except from the point of view of the probable genesis of the mineral, is that known as the Guadalupe, which lies inland about one mile from the shore of Guadalupe bay, which is some 12 or 14 miles south from the Punta Aguja, and on the east shore of Concepcion gulf. The other deposit, known locally as the Gabilan, is on the east side of the peninsula, and about 14 miles across country from Guadalupe. Concepcion gulf and Guadalupe bay are well protected from storms, but on the eastern shore, which is exposed to the violent storms of the Gulf of California, great fear is expressed

MANGANESE IN JOINTS AND CRACKS, GABILAN.

by the mariners, and danger of the *Nord Oeste* is constantly dinned in the visitors' ears—partly with a view to getting more pay for conveying passengers, but principally from the fact that the coast is rough and forbidding, with hardly any inlets or coves and no harbors.

The entire peninsula in which the manganese is found consists of igneous rocks, from extremely basic basalts on the east, overlain by agglomerates and conglomerates, with later intrusive sheets or sills of trachytes and andesites, and in certain localities pyroxenites. There appear to have been several distinct periods of intrusion and uplift, which, in addition to tilting the superincumbent conglomerates, have cracked the earlier basaltic and trachytic rocks. The direction of the intrusion is about north-northwest, and very probably is the cause of the peninsula. In the Guadalupe there are a series of deposits or layers, which at first appear to be regular veins, but I am inclined to believe they are local deposits where manganese-bearing solutions have found ready channels, or have precipitated as deep-sea deposits, the currents or flow being slow, and the adjacent rocks favorable to such deposition, and in this way the manganese oxide, accompanied by more or less silica, iron, and lime as sulphate (gypsum) has formed the layers referred to. The Guadalupe deposit, to my mind, has no commercial importance at this time, as, although at first sight it appears to be an exposure of over 100 ft. wide, subsequent investigation proves it to consist of several layers or beds, separated by layers of barren rock, composed largely of impure iron-stained gypsum. Erosion and weathering have caused the removal of the softer barren material, with the result that a large area is covered with black float, the average tenor of many samplings of the material 'in place' being as follows:

17.54% Mn (metallic);
1.63% Fe;
3.61% CaO (as sulphate);
28.22% SiO_2.

Across the peninsula at the point called Gabilan, the occurrence of the magnanese is entirely different. There is a cementing or filling in the brecciation cracks of the surrounding and enclosing pyroxenite. My impression is that these deposits are the result of metasomatic processes, or in other words the replacement of some of the original constituents of the basic rock, and a filling of the cracks by the material leached out from some of the component minerals of the rock. For example, augites or monoclinic pyroxenes are highly developed, and it is known that schefferite in its original form carries manganese, combined with lime, magnesia, and iron as a silicate. The remarkable purity of the manganese oxide in the Gabilan section compels me to believe that practically the manganese only was extracted from its original crystal home, and redeposited in the fissures and cracks which exist, completely filled, from knife-blade thickness up to as much as 11 inches. This material, on analysis, proved to contain from 59.9% to 60.34% of metallic manganese, with not more than 0.25% Fe, no lime, and 1.5% siilca.

This brecciated manganiferous area extends along the coast for over a mile, and is exposed inland in several places for 500 ft. from the shore-line, and at the time of my visit to the place the entire coast for this distance was strewn with pebbles, boulders, and fragments of sea-washed pure ore, samples of which equaled the analysis just referred to. It is difficult to estimate the tonnage of the ore on the beach, but it will probably exceed 2000 tons, and might be double that amount.

In reference to the probable genesis of the manganese in this locality, which hardly comes within the province of this paper, I would refer to 'Geological Distribution of the Useful Metals', by S. F. Emmons, *Trans.* Amer. Inst. of Min. Eng., 1893, Vol. XXII, pp. 53 *et seq.* As the Gabilan is absolutely undeveloped, it is impossible to say with any degree of accuracy what the ratio of pure manganese-filled cracks to rock-mass is, but I estimate that it occupies from 2.5 to 4%, allowing a length of 5000 ft. along the shore line, by 30 ft. in height of cliffs above tide, by a width of 500 ft. back from the shore, this would indicate a workable tonnage of 5,750,000 tons, which should produce 144,000 tons of clean ore, if the average tenor of this block only runs 2.5 per cent.

Probable water issuing from a contact of a trachite and agglomerate exists in a good spring at a point on the coast known as Trinidad. This is about 4 miles from the Gabilan deposit and indicates a permanent water-supply, as there are several large date palms growing around the spring, within a few feet of the beach. The locality lends itself to easy transportation, but before any extensive work is done, the tract should be carefully prospected, and several hundred tons of the cliff shot down, and for the purpose of preliminary estimates, hand-picked, to determine the average manganese content. If this should prove satisfactory, larger operations can be undertaken, a fair-sized supply-ship could be bought or chartered, and this could be used for the transportation of the water, men, supplies, and ore as mined and sorted. A further equipment of dugout canoes, such as are used along the Pacific and gulf coasts by fishermen and pearl divers, should be bought, as these are the only craft that are suitable for landing on this rocky coast.

In large operations the waste rock could be used for the building of breakwaters and small harbors, and in this way make a series of refuges, not only for the operatives on this work, but for the many small coasters and sailing craft that are now in constant dread of the northwesterly gales. It has been remarked that if you are looking for a rare mineral, go to Lower California: and certainly, for exceptional purity of manganese in considerable quantity, I would commend the peninsula of Concepcion.

Thorium Syndicate Suspended

For a considerable time past negotiations have been proceeding among the principal European manufacturers of thorium with the view to coming to an agreement by which production and prices could be regulated, but these have at length been abandoned, as unanimity was found to be unattainable under existing circumstances. The supply of thorium was at one time a virtual monopoly under the control of a powerful Continental syndicate, but the 'corner' has at length been broken, and the industry has fallen on evil days from the producer's point of view. Prices have steadily declined for two or three years, and are not unlikely to go considerably lower. This declining tendency is directly attributable to the glutting of the market with monazite sand, the principal raw material from which thorium is produced. The supplies of this sand were entirely controlled by the syndicate, whose exorbitant prices forced the leading makers of incandescent mantles, including the incandescent-light companies, to exert themselves to obtain independent supplies at all costs. In this they were successful, and prices fell rapidly. Practically the whole of the supply of monazite sand comes from Brazil, and thorium nitrate is manufactured only in the United States and on the continent of Europe. The yearly consumption of monazite sand for the manufacture of thorium is placed at between 2000 and 2500 tons, but for some years the supplies have been equal to double the consumption. The contract between the Brazilian Government and the thorium syndicate has now expired and a new lease of the fields is about to be arranged. There are numerous offers, and as the Brazilian Government is not likely to allow any monopoly to acquire control of the supply, a further flooding of the market and consequent decline in prices is feared.—*London Financial Times.*

CHROMITE is used extensively in the manufacture of ferrochromium, employed for making special steels, alone or in combination with tungsten, manganese, nickel, or other steel-hardening metals. It is also used for lining copper, lead, steel, and other furnaces, where the corrosive action is very great. For this purpose it is used either in the crude form or as chrome brick.

One Use for Tailing

Representatives of four railway systems entering the new Union station at Joplin, Mo., joined with the Joplin Commercial Club and the city council recently in celebrating the opening of the station, which is built of reinforced concrete made from tailing from the zinc mines. The gravel from the jigs and the sand from the concentrating tables, the two forming 15 parts in a mixture of 22 parts, were mixed with river gravel and sand, 3 parts, and portland cement, 4 parts. This formed a concrete which, when poured into moulds containing reinforcement, formed the solid walls, floors, and roof of the station, shown in the accompanying illustration. The demand for tailing as a building product is increasing rapidly, and thousands of tons are shipped out of the district each month. The tailing is used in concrete for constructing buildings, viaducts, telephone poles, railway ties, fence posts, burial vaults, and numerous other structures. As more than 95% of the material passing through the concentrating plants of the Missouri-Kansas-Oklahoma district consists of flint or limestone, and as an even greater percentage is waste, when the vast amount of boulders, that are discarded before they reach the mill, is taken into consideration, it can be realized that the production of so-called waste each year is very great indeed. A conservative estimate would place a single year's production of tailing at 6,750,000 tons. Not only is this being employed as a building material, but vast quantities of boulders are utilized in the construction of dwellings, garages, electric-line stations, etc. At present Harvey Nash, the city collector of Joplin, is erecting a $3600 bungalow built of huge boulders secured from a mine dump.

UNION STATION, JOPLIN, MO., BUILT OF ZINC-MILL TAILING.

Copper Deposits of the Nizina District

The most valuable copper deposits known in this region are situated near or at the contact between the Nikolai greenstone and Chitistone limestone. The copper is not, however, restricted to that horizon, but is found in many parts of the greenstone and even extends into the limestone to a distance of at least 1000 ft. above its base. The Kennicott or Bonanza copper mine, which made a first shipment of 1100 tons of ore to the Tacoma smelter early in April, is described in a report on the Nizina district, by F. H. Moffitt and S. R. Capps, of the United States Geological Survey, as well as other near-by copper properties, including those on the northward extension of the Bonanza fault, the Nikolai mine and the Westover claim, on Dan creek. An important fact concerning the copper ores is that they are connected with faults and shear zones, many of which, though difficult to recognize, give opportunity for the circulation of copper-bearing waters and the deposition of their copper. The Bonanza mine is on a large deposit of chalcocite located in such a shear zone. This shear zone has not given rise to any important displacement of the rocks on either side and was traced north-northeast for a distance of more than a mile from the Bonanza mine.

Peace in the German Potash Industry

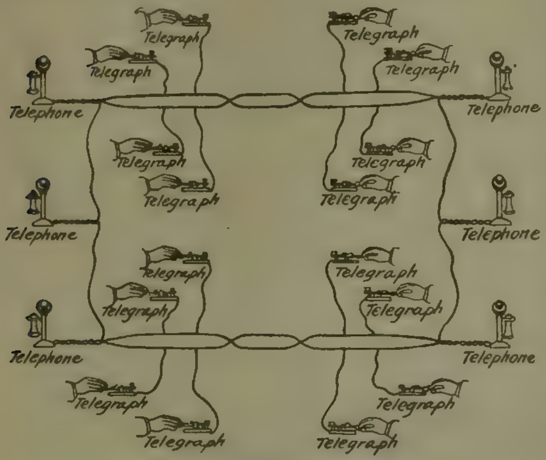
At the conference held recently at Hamburg between the conflicting interests, German and American, in the potassium industry, an agreement was reached as to prices and rebates. The agreement has a duration of five and one-half years. During this period the American purchasers of potash, that is to say, the North Trust, the South Trust, and the independents, obligate themselves to make all purchases from the potassium syndicate. The probability of the market being disturbed by outside mines is thought to be remote, as such outsiders would have to organize a sales agency in the United States similar to the German Kali Works owned by the syndicate, which delivers potash salts directly to the buyer. Such an organization would be expensive and difficult to effect.

The basis of prices is practically the same for concentrated salts as that provided in the potassium law, and the same as prevailed in America in 1909 before the syndicate was renewed and before the Schmidtmann contracts went into force. The prices, aside from 40% manure salts, which are sold to the German agriculturists at low prices, are the same as the maximum prices laid down in the law for the domestic consumption. On the other hand the prices proposed for raw salts, especially kainit, are higher than the prices formerly paid by Americans to the syndicate. Rebates for most sorts of salts are increased. Formerly a rebate of 9% on the average was granted the American companies. Now it will be from 11 to 12%. In reference to certain expenses which may be incurred by the syndicate, the right is granted it, during the duration of the agreement, five and one-half years, to increase prices 3%. The agreement is incomplete, inasmuch as the Aschersleben and Sollstedt works, belonging to the Schmidtmann interests and the Schmidtmann International Trust have not united in it. An effort will be made by amicable means to bring the remaining parties into the agreement. If it is not successful, it is thought that their sales contract will be attacked, as they are regarded as in some respects legally indefensible.

At a recent general meeting of stockholders of an important mining company held previous to the aforementioned conference at Hamburg, the president stated that the favorable result of the business year, namely, the distribution of the dividend of 15%, had been attained in spite of the potassium law. The chief purposes of the law, the prevention of the precipitate founding of new works and the rendering ineffective of the alleged ruinous American contracts, have not been accomplished. In both of these directions the law has proved abortive. Directly contrary to the law, a much more active founding of new companies has taken place and the American (Schmidtmann) contracts are in full force. This opinion seems to be shared by persons in Brunswick acquainted with the condition of the potassium industry; it is said that the industry has been sustained by the steady increase of sales in old markets and the introduction of the salts into new markets.—*U. S. Consular Report.*

Multiple Telegraphy

Many engineers will be interested in the following description of the method of using a circuit for both telephone and telegraph messages. It is taken from the annual report of the American Telephone & Telegraph Co. A telephone 'circuit' consists of two copper wires of superior construction, arranged in a particular relation to each other, forming a metallic circuit equipped with auxiliary apparatus, loading coils, etc., connected with a switchboard—all very complicated and elaborate. A telegraph 'circuit' consists of one wire at most—a grounded circuit. This wire can be divided into several distinct circuits. A telephone 'circuit' can not be used for telephone purposes by any but the two persons in communication, during the time of such communication, but the same telephone circuit can, at the same time it is being used for telephone service, be divided into two, four, or even eight telegraph circuits, each of which can be used for the transmission of telegraph messages. While existing telephone toll and long-distance lines can be used for telegraph purposes, the existing telegraph lines can not be used for telephone toll and long-distance purposes until reconstructed and arranged as described above.



WIRING FOR MULTIPLE TELEGRAPHY.

Use and Care of Mine-Rescue Apparatus

By James W. Paul

*Miners 22 to 45 years old, in good physical condition, who are temperate in their habits and naturally calm and deliberate are best suited for mine-rescue work. Before a man undergoes training in the use of breathing apparatus he should be examined by a physician to ascertain his physical condition, especially the action of his heart and lungs, and any defects of the nose or throat. Unless a man has a physician's certificate stating that his physical condition is good, he should not be permitted to take rescue training, nor to attempt rescue work in a mine.

A rescue party should have not less than five, and better not less than six members. Only such persons should be allowed to join the party as have already been trained in the use of the apparatus and are equipped with rescue apparatus in good order and have agreed to follow the directions of the leader, who must have full charge. While working in unbreathable gases within a mine the men should keep close to one another, and not separate under any condition. To be efficient and successful a party must take every precaution for its own safety. If one person in a party faints or receives an injury he becomes a burden instead of a help, for the entire party must at once conduct him to the surface or to fresh air. One or two stretchers should always be at hand.

A relief station, or base of operations, should be established at the end of the good air, and a relief crew with knapsacks should be stationed there ready to put on their apparatus and start at a moment's notice. A patrol of all brattice and doors leading up to the relief station should be maintained to protect the relief crew from harm. At each large mine there should be at least four crews, two outside and two inside crews, each of six men, including a captain and a lieutenant, and these crews should have practice once a week. While working in dense smoke the members of a crew should hold a rope which leads to fresh air. In case of total failure of an apparatus to supply breathable air, the wearer of the apparatus can throw away all the parts but the oxygen cylinder, and breathe from the cylinder through his mouth while endeavoring to reach fresh air with the rest of the crew. Apparatus for giving oxygen to one who has been overcome with gases is an essential part of the equipment of a rescue party. A telephone helmet is a convenience for shaft work, and its presence lends much confidence to a rescue party. Electric lamps, safty lamps, gas-analysis apparatus, thermometers, a pocket compass, and a map of the mine are necessary parts of the equipment. At each training station a record should be kept showing the work done by the men and the difficulties encountered. A record of each apparatus should be kept also. If an apparatus fails to give proper service it should be subjected to the regular tests, unless some injury is seen by inspection.

The United States Bureau of Mines has established a regular course of training in the use of mine-rescue breathing apparatus. This training is designed to give miners or other persons connected with mining a knowledge of breathing apparatus in general, and a confident familiarity with those types of apparatus that are most apt to be used in this country. The purpose of the Bureau of Mines in establishing this system of training is to facilitate investigation work within mines in which disasters have occurred, and to make mine-owners and miners acquainted with the value of breathing apparatus for rescue operations after mine disasters. It is hoped that, as a result of this work by the Federal Government in the near future, men familiar with such apparatus will be scattered throughout the coal-mining centres of the country, and be available on short notice to assist in rescue operations. After a disaster, valuable time is often lost in training men at the mine before rescue parties can be organized. Furthermore, a man can not work efficiently unless he has thorough confidence in the apparatus. To give a man this confidence, the course of training has been planned in such a way that he must do work in poisonous or unbreathable gases for periods of one and two hours at a time.

Copper Producers' Association Report

The Copper Producers' Association reports stocks on August 1 as 137,738,858 lb., a decrease of 19,695,306 lb., as compared with 157,434,164 lb. on July 1. The domestic deliveries in July were 56,982,582 lb., compared with 61,655,561 lb. for the previous month and 56,708,175 lb. last year. Exports, 74,880,658 lb., compared with 71,460,519 and 59,407,167 lb. Total consumption, 131,863,240 lb., compared with 133,116,080 and 116,115,342 lb. The total production in July was 112,167,934 lb., compared with 124,554,312 lb. in June and 118,370,003 lb. last year.

The Grand Trunk Pacific is spending $17,000,000 this year in constructing some thousand miles of new track. It is stated that 10,000 men and 4000 teams have been engaged. There is keen competition between the Grand Trunk Pacific and the Canadian Northern as to which will first reach the Pacific coast. Up to the present the grade on the main line has been carried almost to Tete Jaune Cache, a point about 1100 miles west of Winnipeg, while steel has actually been laid as far as Fiddle creek, about 80 miles east of Tete Jaune Cache.

---

*Abstract from Mines Circular No. 4, Bureau of Mines.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Liberty Bell Mill

The Editor:

Sir—With reference to the description of the Liberty Bell mill, appearing in your issue of June 24, certain statements have received wrong interpretation, so wrong, as to demand correction and explanation.

In saying that the apparent loss was 2.5c. per ton of dry ore, I referred to dissolved metals only, and had no thought that this would be taken as applying to the undissolved value in the ore. In the text reference is made to page 742 where a table showing the tailing value is given, and, had this been referred to, there would have been no ambiguity.

In the tabulation of mill costs the word 'Supplies' was omitted in the lower part. This has led to wrong statements as to the costs of a certain step in the process.

CHARLES A. CHASE.

Telluride, Colorado, July 26.

Overvaluation of Prospects

The Editor:

Sir:—It would seem clearly apparent that generalization as to what is truly a mine and what only a prospect can be of little value to anyone. Usage creates and tends to conserve the words of a language, and their meaning and application, and is apt to make 'mine' mean 'Mine', regardless of attempts at restriction. It may, perhaps, be safely stated that the complained-of confusion in the public mind as to mines and prospects and their valuation, results quite as much from noted mines suddenly becoming scarcely prospects, as from the oft-happening raw prospect suddenly becoming, at the grass roots, so to speak, the million-dollar mine. Certainly, in any attempt at rules for the classification and differentiation, there must always be taken into consideration the elements of time, place, occurrence, and *metallurgical environment*.

The old concept associated with the meaning of mine—of working or producing—will probably survive, regardless of attempts at technical limitation; at the same time any effort to classify investors into classes differently possessed of the common human attributes will probably fail. That the big investors of London and the money centres are just as much afflicted with the human trait of speculative hope as are the much-berated owners of prospects, is abundantly demonstrated; nor is this changed by the many negative blunders made by their highly paid experts in missing mines, to their regret.

A 'Goat Ranch' prospect, of black-looking limestone, known for years to carry some little gold along with some manganese and iron, suddenly becomes a quarry mine without either shaft or drift and produces a fortune because the new smelter pays the cost for mining and transportation for the flux, and returns as profit the low silver and gold content otherwise valueless. In plain sight on another mountain, a fortune is paid by a foreign syndicate for a property, after the most extensive expert examination of measured ore according to the rules, and after a few months' extraction the property becomes, due to an unforeseen condition, in exactly the same 'prospect' state of hunting the ore, by miles of drifts, as the adjoining property that has as yet never shipped. How would the 100-ft. depth rule work, where the contact body between the lime above and the andesite below goes up and not down? At Joplin, or in the porphyry coppers, a few drill-holes means a mine in the commercial sense of the word, without the three-sided ore. In Santa Eulalia, near the productive mines, fortunes are paid for ground with but scarcely a sign on the surface, although it may mean another fortune to prove the ore. Such prospective property, regardless of rules, is much sought after by syndicates of wealthy and world-wide experienced owners, and their engineers, and the failures seem not to deter the speculative hope created by the plums.

As it is stated that at least 80% of the big mines of the world have produced 'from the grass roots', prospects of this type may be considered as at least not unworthy of examination, especially if in proved districts. The price placed upon prospects that express either the capitalization of the owner's hopes or his overconfidence in his superior and exclusive prophetic vision, are certainly human traities that are apt to beset all alike, and one can easily allow for and excuse this, especially in the ones that have nursed the fever for years. Against this common overvaluation of prospects, let us set the wide literature of the London millionaire's years of dividends against the locator's years of search rewarded only by his 'mess of pottage'. Again, no doubt, market overvaluation of stocked mines helps as much as anything the exaggerated ideas on the part of the owner of prospects. Whether mine or prospect, one, two, or three-sided ore, or no ore exposed at all, the time, place, occurrence, and metallurgical environment are necessary determining factors of valuation.

Chihuahua, Mexico, July 27. L. L.

Dredging Costs and Methods

The Editor:

Sir—In reply to your correspondent who is interested in dredging costs and methods, I can give a brief description of the harbor work in the Key Route basin now being done for the city of Oakland.

The project involves the construction of a water-front street along the line of the levee now being built, and the reclaiming of the area on the landward side of the street by filling with spoil from the dredging required in order to deepen the harbor and its approach. The dredging of the harbor is to be done by suction dredges, as stated by your correspondent, and a levee was required to prevent the spoil of the suction dredge running back into the harbor. In firm material and still water such a levee could be, and often is, built by a clam-shell dredge; but with soft material on the site, and the strong tidal currents existent, this simple plan was impracticable. Therefore the city is forming and protecting the water face of the levee by a wall of loose rock, behind which the mud is placed. The rock of this wall has been criticized as being too small, and undoubtedly larger pieces would make a more stable wall. But as this wall will never be exposed to wave-action of any serious violence, and as it must retain a fill which is in part nearly liquid, the material used is efficient and cheap, if not ornamental. The rock wall is built under city supervision, and the contractor paid by the ton of rock placed.

A separate contract was let for the building of the earth levee, the contractor to use any method he chose, subject to the approval of the City Engineer. Material was to be taken from the harbor, leaving a berm on the waterside of the levee, and the amount of work done by the contractor ascertained by measurement of the excavation made. This is a common method in civil engineering work, and the only feasible one in the present case. Counting the number of buckets of material handled would result in a very rough approximation of the amount, as they are sometimes piled to nearly twice their level-full capacity, and in hard material may not be more than a quarter full. The temptation to use partly filled buckets is obvious. Measurement of the levee is impracticable, because it is too soft to walk on, and it is easier to cross-section the excavation than to wait for tides high enough to get a decent cross-section of the levee by sounding. The excavation of material for the levee naturally results in a channel parallel to it, and the city has just so much of its harbor work done. Cross-sections are taken every 50 ft., as close in front and behind the dredge as possible, so that the contractor may not suffer from short measurement, owing to the inevitable rising of the bottom adjacent to the levee, as its weight increases. This rising of the bottom adjacent to a fill is a familiar phenomenon, and will continue until the material under the levee is firmly compacted. The rate of rising is already decreasing, as shown by the cross-sections taken.

The question of costs is too complicated to be dealt with in a letter, and "a little knowledge is a dangerous thing." It is obvious that the character of material to be handled and the length of haul or discharge are two of the principal factors influencing cost; in the case of a suction dredge the height of discharge also affects the power required. The fixed charges of moving plant, etc., raise the unit cost in small jobs. Impounding levees for the spoil forms another variable item. The weather and water conditions affect the cost largely—in some localities it is impossible to count on more than fifteen days a month. The only way to get an approximate idea of the cost of any particular work is to have an estimate made by an experienced dredge-man or engineer.

Dredges similar to those commonly used for gold dredging are sometimes used in harbor work; they are called 'ladder dredges' in civil engineering works. They are more common in English and European practice than in American. So far as I have been able to discover, no tests for gold have ever been made in the Key Route basin, or near by. M. H. P.

Oakland, August 2.

Mine Valuation

The Editor:

Sir—Many phases of this important subject have been lately discussed in the *Mining and Scientific Press* by able writers, so that perchance but little can be added, except in so far as a few instances of personal experience may be of interest to those who specialize in this branch of the mining business. One engineer asserts that sampling is a purely mechanical performance, calling for but little experience; but the interpretation of the sampling results, he says, calls for a large fund of experience. This does not look rational to me. Should the sampling be faulty, due to inexperience, the sampling results will be equally so, and so, quite naturally, will be the final interpretation by the man of experience. I venture to say that no results can be depended upon as absolutely reliable unless the sampling was performed under the personal supervision of men of experience.

In estimating the ore in a mine, the term 'ore in sight' or 'positive ore' is sometimes used rather loosely. Taken literally a block of ore exposed on three or more sides is not ore in sight, as meaning the whole volume of ore in the block, because only a very small percentage of this is under actual observation. In most mines high-grade patches and low-grade spots alternate with barren zones of irregular dimensions within the ore-shoot. Fortunately nature has left certain indications in the exposed parts of the mines where these conditions obtain, which can be interpreted by the experienced valuator. To give an illustration, I once sampled a mine in the Bendigo district, Australia, in which the vein occurred as a blanket or saddle outcropping entirely around a low hill. The mine had been extensively worked, but was idle at the time. I found a block of ore estimated at 30,000 tons exposed on four sides by drifts, while the stoped-out area entirely surrounded this block. The vein, after being sampled in 3-ft. cross-sections, was found to be of a profitable grade. Not being satisfied, I started an intermediate drift into the orebody, and after advancing 20 ft. through pay-ore, found the vein barren, though as strong as ever. This was repeated on the other three sides, with the result that the whole of the interior, with the exception of an exterior shell of pay-ore about 30 ft. in width, consisted of barren quartz. Instances of this kind are by no means rare, but can usually be guarded against by careful and accurate observation.

In the sampling of precious metal mines where a large percentage of the metal is in the native state, which generally presupposes a patchy character, hand sampling will, as a rule, give negative results. An ore dump, if measured relative to the amount of vein matter extracted from the workings, will give far more reliable data, as in this case the dump material can be worked down in large quantities. Mill tests on a large scale cannot always be had, but where such tests can be secured even on small representative parcels, the results will be more accurate than those that can be got from hand sampling. A prominent gold mine in Colorado gave subnormal results when sampled in 3-ft. cross-sections on blocks exposed 50 ft. square, according to T. A. Rickard. At the Bunker Hill & Sullivan mine I was told that systematic hand sampling, long since discontinued, gave negative results in proportion to the area stoped.

Some time ago I sampled a gold property where 80% of the metal is free and the gangue is ideal for cutting grooves, that is, neither too hard nor too soft. Results from hand sampling were extremely low compared to the value of the dump. A small mill in the vicinity happening to be idle, sampling began in earnest. Drifts and raises were driven through the blocks and all of the ore milled, with results more than satisfactory and closely tallying with the assays on the dump. The unaccounted difference between sampling and mill results might possibly be accounted for in a few instances. In one of the largest camps on the Mother Lode I have only recently observed men rocking the tailing on the creek bank below the mills. On panning the sand my wonder turned to surprise. In Mysore, India, 12 years ago, the sand below the mills also had an unaccountably high content. No doubt in many large low-grade mines it is good practice to consider the tonnage crushed at the expense of a percentage of the metal content. Whether sampling for the purchaser or the vendor, the valuer should in no wise be influenced by personal considerations; to introduce one factor of safety in the first case and use a different one in the second can hardly be conducive to an unbiased judgment.

R. L. Mann.

Cazadero, California, August 4.

Oxy-Acetylene Welding

The wide possibilities of use in connection with field repairs at mines lends especial interest to the description below of tests of the oxy-acetylene welding process.

A demonstration of the oxy-acetylene blowpipe was given at the Sydney Technical College recently by George Kennedy, formerly leading blowpipe operator with the British Oxygen Co., Ltd., of London. A number of representative engineers being present, several welds were successfully made, and afterward stood all tests to which they were subjected. The cutting powers of the blowpipe were also conclusively demonstrated.

One of the principal advantages of the blowpipe system of joining metals by simple fusion is that as the heat can be locally applied, the parts of complicated structures can be fitted together and welded in position. In many cases electric welding has hitherto been the only possible substitute for mechanical joints, the blowpipe can be more profitably employed, and in a large variety of work the blowpipe can be used where electric welding is impracticable.

Autogenous welds can be effected by means of the oxy-acetylene blowpipe without any deleterious effects upon the metal. The heat, in addition to being greater than that obtainable from any other blowpipe system, is also more concentrated, the temperature of the flame in a good oxy-acetylene blowpipe being approximately 6000° Fahrenheit.

During the last few years oxygen has come prominently into use for the purpose of cutting wrought iron and steel plates and structures of all sorts. The process is based on the well known fact that a jet of oxygen directed upon a previously heated spot on metal ignites it, with the result that the metal, acting as its own fuel, burns away rapidly in the form of oxide of iron.—*The Mining and Engineering Review.*

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

A GOOD FILLER for woodwork is composed of corn starch, $^1/_2$ lb.; fine pumice-stone dust, $^1/_2$ lb.; white polish or liquid shellac, $^1/_4$ gill, boiled oil, $^1/_4$ pint. Thin for use with turpentine.

A GENERAL RULE for the diameter of the base of a brick chimney standing free is that the side of a square chimney or the diameter of a round one should be one-tenth of the height.

SALT is obtained from three principal sources: (1) from rock salt, in which case it is mined, and crushed; (2) from brines pumped from wells; (3) from the evaporation of sea-water. The salt supply of Utah and the adjoining States is obtained by evaporating the waters of Salt Lake.

BROMINE and bromine salts are produced as a by-product of salt manufacture in the United States, the Michigan wells being the most notable producers. Although only a small quantity of bromine salts can be obtained per ton of salt, the difference in the consumption is so great that the supply of bromine and its salts is ample to meet the demand. If the demand were greater the selling price would probably be lower.

A STRAP WRENCH suitable for unscrewing lubricator bodies, glass oil-cups, and other polished articles, can be made from a piece of hardwood one inch square and a foot or more long, a metal dog, and a piece of sheet brass, which acts as a bearing for the dog and as a clamp to hold the strap against the wood. To use the device, pass the strap around the object to be turned and pull the end through the dog as far as it will go, then turn.

AN ACT of 1907 (35 Stat. L. 1243) provides "that during each year and until patent has been issued therefor, at least one hundred dollars' worth of labor shall be performed or improvements made on, or for the benefit or development of, in accordance with existing law, each mining claim in the district of Alaska heretofore or hereafter located." There is no warrant for the belief that six claims can be held by the performance of $100 worth of work yearly.

HIGH-CARBON STEEL should not be used for reinforcing concrete, as from its greater brittleness it is liable to sudden failure under stress, and is frequently found to be cracked or broken when sent to the work, making careful inspection necessary to prevent bad material getting into the structure. High-carbon steel is supposed to permit much higher working stresses, but much of the material sold as such, when tested, will not come up to specification.

BUILDING STONES have to meet various requirements; for example, such a stone should be durable, of pleasing appearance, comparatively easily cut, cheap, and available in large amounts of uniform quality. It might be expected that a stone which could be easily cut would not be durable, but fortunately many building stones have 'quarry sap' in them; that is, they are easily cut when first quarried, but on standing and drying out become much harder.

AN OIL-CUP attached to a lathe centre will prove a great convenience and will prevent the centre becoming hot. A $^1/_{16}$-in. hole is drilled in the point of the centre and carried back about 1¼ in., or far enough to meet the vertical hole, which is tapped to receive the oil-cup. It is obvious that the point of the centre will have to be removed before drilling the $^1/_{16}$-in. hole, but this will not decrease the bearing surface of the centre, as the extreme point never touches the work if the centre hole has been properly made.

A VERY useful spacing instrument is made from an ordinary thread gauge with the teeth blackened by rubbing over a lead pencil. By moving the blade sidewise about $^1/_{16}$ in. a fine hair line is made by each tooth, thus dividing the line into equal parts, which may be made fine or coarse by using different blades of the thread gauge. If the teeth are rubbed on a pencil each time after being applied to the paper, the resulting divisions will be very distinct. Every draughtsman who has frequent occasion to draw threads or other work requiring spacing, would find the purchase of a thread-gauge a good investment.

ORES may be smelted in reverberatory-furnaces fired by gas, but under ordinary conditions it is not practicable to do so. Gas furnaces, to derive the full benefit of gas firing, must be regenerative, which is equivalent to saying that they must be large and of expensive construction. Such furnaces are widely used in the manufacture of open-hearth steel, and the tendency toward their application in reverberatory copper-smelting is shown by the growing use of oil and coal-dust fired furnaces for that purpose. It is not unlikely that the small-sized gas producer may soon be successfully applied, in which case the use of gas for reverberatory smelting is likely to become widespread.

PATENT OFFICE drawings differ in many ways from an ordinary working drawing, and before attempting to prepare them, the draughtsman should study the 'Rules of Practice', of which a copy can be obtained on application to the Commissioner of the Patent Office. Among the peculiar features of patent drawings are the non-use of centre lines, the absence of scale in the ordinary sense, and the incorrect way of drawing certain parts. Two points which should be kept in mind are: (1) that the drawings are intended for the use of persons who are not accustomed to reading workings, and (2) that poorly prepared drawings may be the cause of losing a patent suit.

METHODS of mine and smelter bookkeeping are as varied as the methods followed in mining work, and it is impossible to settle on any one system as the best, except for a given set of conditions. When the scale of operations is small, all the records can be easily kept in a few books. Where operations are extensive it often happens that a large force is engaged in keeping a large number of books, without making much information available, simply because the information needed is not readily obtained from the records. An accountant who has had experience in mining work is more competent than an engineer to decide upon the necessary system. A large part of the difficulty experienced is often due to the fact that the system adopted at the beginning when the scale of work was small, proves inadequate in later years, and the introduction of an entirely new system is attended with difficulty.

IN leaching ores with cyanide solution, the solution may either be allowed to flow from the top downward, or forced to flow from the bottom upward, overflowing at the top of the vat. Any ordinary force-pump will serve to force the leaching solution into the space beneath the filter-bottom of the leaching vat, whence it passes upward through the ore. In either case care must be taken to get an even distribution of the ore in the leaching-vat, otherwise channels will be formed, and the leaching will be imperfect. Channeling may be more easily avoided when downward leaching is used, as the solution automatically finds its way by gravity through the ore at the proper rate. Where pumping is employed the solution may be forced in faster than it can pass, and the excessive pressure will cause channels to form. It is believed in some quarters that the use of upward leaching gives a more thorough contact of solution and ore, but this is a matter of opinion.

Special Correspondence

BUTTE, MONTANA

Increasing Use of Electric Power.—New Mill for Butte & Superior.—George Mine Scandal.—Prospects for Copper.—Work of Smelter Fume Commission.

The Anaconda Copper Mining Co., owner of the Butte, Anaconda & Pacific railway, has decided to electrify that road, which, with main line and main spurs is about 80 miles long. The plans have been approved and the change will call for an expenditure of about $1,000,000. The work of installing an electric haulage system in the mines of the Anaconda company is also progressing, and electricity is being put in all the properties, gradually taking the place of steam everywhere. The compressed-air hoisting plants at the Mountain View and Diamond mines are in operation and the new system is being installed at the High Ore mine. Nearly two months was consumed in making the change at the Diamond. It is also announced that the Chicago, Milwaukee & Puget Sound railway, from eastern Montana to the Pacific Coast, will be operated by electricity, and the railroad company has for some time been negotiating for electric power. It is likely that the Amalgamated Copper interests, which own the big power plant at Great Falls, will supply the Milwaukee with electric power, although they have not yet been able to agree on rates. The Milwaukee also contemplates making electric lines of several proposed branch lines in Montana.

It is announced as official that the Butte & Superior Copper Co. will build a concentrator of its own near the Black Rock mine, although it is yet uncertain when work will be started. The company has for several months been experimenting with flotation methods of concentration, known as the 'gas bubble' method, at the Basin concentrator, and it is announced that the system works well on Butte & Superior ore, the claim being that it saves 90% of the valuable minerals in the ore, against a saving of only 65%, and consequently a net loss in operation, under the old system. The initial capacity of the new concentrator is to be 500 tons per day. D. C. Jackling has passed on the new concentration and says it is successful. However, there have been so many and repeated claims in behalf of Butte & Superior in the past that did not 'pan out' that everybody in Butte is a Thomas and registers from Missouri when anything is given out about Butte & Superior.

The George mine, near Anaconda, which was reputed to have fabulous wealth in silver, has been closed and the plant dismantled by the men who had a lease and bond on it. Apparently there is a remarkable case of 'salting' or jobbery in connection with the George, and a great scandal in connection with one of the big smelters is being hushed. When the men who took the bond on the George were negotiating for the property they were furnished with smelter figures showing very high returns, but the best ore they have been able to find in the property since has netted about $4 per ton, which did not pay operating costs. The men who held the bond paid only $25,000 on it, however. They sold considerable stock in a company they had organized in anticipation of the big mine they expected to develop. Ex-Mayor Nevin, Pat Wall, formerly of the East Butte, and several other Butte men are among those who have lost money in the deal.

Before leaving for the East, J. D. Ryan, president of the Amalgamated company, reiterated his faith in the future of the copper industry. With the rapidly improving domestic demand the copper situation of the near future looks very good indeed. L. D. Ricketts, general manager for the Greene-Cananea Copper Co., and J. A. Holmes, Director of the Bureau of Mines, have completed their investigations of smelting conditions at Anaconda, and J. H. Hammond, the chairman of the commission, will make an independent inspection during August. The three men will then formulate a report and may be able to make suggestions that will result in improving the situation, although the Anaconda company has done everything possible to lessen the damage from the smelter fume.

JOPLIN, MISSOURI

Mining Beneath the Bedrock. — Noticeable Discrepancy in Prices of Spelter and Blende.

Numerous rich finds of zincblende in the Thoms Station district, north of Joplin, have done much toward exploding the theory that the pay-dirt of the district is underlain by a bedrock of limestone, beneath which it is useless to prospect. Because of this antiquated theory, Thoms Station, which is now producing more than half a million pounds of zincblende each week, remained dormant for years, after an early boom when rich ores were found near the surface and above the bedrock. Crossman, O'Donnell, and others have taken a lease on land in this area, and in the first drill-hole, sunk within 20 ft. of an abandoned shaft, ore was found at 110 ft. and continued for about 12 ft. A deeper and equally rich run also was found. In other drill-holes the formation was consistently blocked out. Had the pioneer prospector pushed his shaft 20 or 30 ft. deeper, he would have found the bonanza. Throughout the entire Thoms Station district, in which scores of shafts are being sunk, and in which dozens of drill rigs are at work, evidence is found on every hand of suspended operations after the 'grass-root' deposits had been gouged out. The 'bedrock' of the early days, which first was found at 30 ft., then at 50, then at 75, and finally at 100, has ceased to terrify, and the fact is becoming generally recognized that the chances for finding pay-dirt beneath limestone bars are as good as they are in open ground.

Under ordinary conditions the price of spelter at East St. Louis has had some effect on the price of blende, but conditions at present are extraordinary. An 8 to 1 ratio has been considered as fair. That is, when East St. Louis spelter is quoted at $5.65, the present quotation per 100 lb., blende per ton should be eight times as much, or $45.20 per ton, on the assay basis of 60% metallic zinc. Instead of this, the price is now $38 to $42.50 per ton, and little is sold at the latter figure. At times the ratio has been much higher than 8 to 1; at times it has been slightly below this, but conditions have never been so unfavorable from the ore producer's standpoint as now. The average ratio for 12 years has been greater than 8 to 1; 8.13 to 1. At this ratio, blende should now be bringing $45.935, assay basis of 60% metallic zinc, while high-grade lots should be commanding $49. Contrary to precedent, high-grade lots are now in lightest demand, and producers of this class of ore, who customarily find it an easy matter to dispose of their output, are surprised to find offerings few. Absence of co-operation among the producers is one cause for the smelters' advantage. The surplus supply of blende in the district is about 6500 tons, of calamine 700 tons, of lead 800 to 1000 tons, widely scattered.

Tebbets & Co., operating on the Brinkerhoff land, north of Joplin, have sunk nine drill-holes and claim that blanket ore has been found. A shaft has been put down on the main lease, and several sub-lessees are at work. A concentrating-plant is to be erected. The extreme depth of the ore, as indicated in drilling, is 206 ft. The first 'shines' were found at a depth of 90 ft. These operations are in virgin territory, some distance from the nearest producers in Thoms Station. To the north of the Tebbets lease, the Kansas City Southern railway, in blasting a 30-ft. cut in a hillside, found a rich pocket of galena, from which turn-ins have been made. The pocket was soon exhausted, but the find drew a great many operators to adjoining tracts, and any number of gouges are now being sunk for shallow lead deposits. Several have already discovered rich 'chunk' lead, and the ore is being cleaned on hand-jigs. That operators are returning more and more to the soft ground mining is indicated by the remarkable growth of the Joplin camp, in which virtually all of the ore produced comes from open formations. A corresponding decrease is noted in the Webb City-Carterville camp, where virtually all of the mining is in deep 'sheet' ground, where the ore deposits are extensive, although the [illegible] and [illegible] is small, barely 2 or 3% as a rule. [illegible] or 6 [illegible] Joplin, for many years, produced [illegible] of the blende of the entire district. It is now producing [illegible] than 40%, and this in face of the fact that the aggregate production of the entire district is increasing.

Barry county, some distance removed from the zinc and lead mines of the district, is to be the scene of extensive development, the Springfield [illegible] Mining & Milling Co. having filed articles of association at Springfield, Mo. The capital stock is $200,000. The company owns large tracts in Barry county. Prospecting is to be begun immediately. At the Mosley mines, in Newton county, where lead was mined by the Confederates during the Civil War, a 100-ton concentrating plant, one of the finest in the district, is being erected. The company has developed a deep run of zinc ore in drill-holes. Virtually all of the shallow lead was mined out years ago, although occasional pockets are still found.

Rigid mine inspection in Missouri is resulting in decreased catastrophes. A striking contrast is noted between the mines of Missouri, in which State the inspection is thorough, and in Kansas, where little or no effort is made to enforce the mining laws in the metal-mining districts. Twelve big producing mines of the Joplin district are now closed down, by order of the inspector. Various reasons are given for shutting down the plants. The most common reason is that only one shaft is used, while a recent law requires all operators to have two shafts, and these must be connected with drifts. Improper cutting of ground, and removal of pillars also result in speedy action on the part of the inspector.

UTAH COPPER MAGNA MILL, GARFIELD.

SALT LAKE, UTAH

Utah Copper Report Revives Mill Controversy.—Nevada Con. Shows Decrease.—Montana-Bingham Makes New Arrangement with Bingham Amalgamated.

A notable statement in the quarterly report of the Utah Copper Co. is that the stamp-mill sections of the Arthur mill have been permanently closed. This statement comes almost simultaneously with the death of A. J. Bettles, who designed the Boston Consolidated mill (now Arthur plant of the Utah Copper). Before the Utah Copper acquired the Boston, millmen familiar with both plants declared that the use of stamp-mills—an innovation of Mr. Bettles for crushing this kind of ore—had been demonstrated to be far superior to the other system, and that a better saving was being made at a lower cost in the Boston Con. The controversy over this point has been prolonged, and the Utah Copper officials have taken occasion at various times in their official and other reports since the consolidation, to proclaim that the Magna (old Utah Copper) mill was producing better results than the other, and to defend the original mill policy of the Utah Copper management. While the present management presents many figures in support of its contentions, there are high-class millmen who still believe that the Bettles system of crushing the porphyry ore by stamps is the proper method. On the other hand, this is what C. M. MacNeill, president, and D. C. Jackling, general manager for the company, have to say officially on the subject: "The Magna plant was operated for the entire quarter. The Arthur plant was not operated to full capacity, but only to such an extent as necessary to take care of the excess of ore production above the capacity of the Magna plant. The remodeling of the fourth section of the Arthur plant was completed by the end of the quarter, and as the operation of the remodeled sections shows that the capacity of the four now in commission is about the same as the original thirteen sections of that plant, the stamp-mill sections have been permanently closed down. Other sections of the Arthur mill will be remodeled to keep pace with ore production."

Nevada Con. shows a decrease in production and earnings for the quarter ended June 30. Production was 15,677,065 lb., as compared with 18,173,676 lb. for the quarter previous. The ore averaged only 1.59% copper, which is the lowest since the operations began.

The tunnel of the Utah Metal M. Co., which is to connect underground Bingham with the International Smelting Co.'s plant at Tooele, is now about half completed. The tunnel will be about 10,000 ft. long, and it is expected that it will be finished within another year. The work is going ahead from the Tooele side of the range at the rate of about 300 ft. per month. Preparations are being made to start work from the Bingham side, the mouth of the tunnel to be near the Highland Boy mine of the Utah Con. When completed, the tunnel will tap a number of orebodies and will furnish a direct route for the transportation of ores from the camp to the smelter. The cars will be run by electricity, the power being furnished in part, at least, by the flow of water from the bore. This flow is steadily increasing.

An arrangement has been made between the Bingham Amalgamated and the Montana-Bingham whereby the latter will extend for about 4000 ft. into the latter's ground, taking its pay in treasury stock. The tunnel will be continued on through to some ground of the Montana-Bingham which cannot well be reached in any other way. The Alta Con. Co. has been formed by Tony Jacobson and associates to open a group of 11 claims between the City Rocks and the old Emma. A force of men has been put at work. The first act of the new directors of the Columbus Extension was to levy an assessment of 5c. per share, or $15,000. Part will go for debts and part for development. Tintic people are making some comparisons of Cobalt shipments with the regular output of this old camp. Shipments from Cobalt for the week ended July 21 were 15 cars, of which 12 were high grade. Tintic shipments for the week ended August 4 (about the average) were 157 cars, and it cannot be said this was all low-grade ore. Four mines—Centennial Eureka, 38 cars, Iron Blossom and Dragon, 24 each, and Grand Central, 14—each shipped more than the entire Cobalt district. The Chief Con., one of the new Tintic producers, is opening up encouragingly. It has shipped about $300,000 worth of ore, most of it from the 1400-ft. level, recent shipments averaging $50 per ton. The ore has been found in a raise from the 1600-ft. level.

A revival of interest in the Indian Queen property in Beaver county has been caused by the discovery recently made by lessees. They have taken out 750 sacks of high-grade, and are steadily opening up more ore. Favorable reports continue to come from the Harrington-Hickory mine of the Majestic company. The water is decreasing and the silver-lead ore in sight is increasing steadily.

The operations of the Sevier-Miller Mines Coalition Co. are giving encouragement to the believers in the Piute county gold veins. The property, formerly the Sevier Con., has gone through the hands of a receiver, and was acquired by the present owners about two years ago. They have been developing the ore, remodeling the mill, and installing a filter-press, making many other improvements, and will soon be ready to start up the 100-ton concentrating and cyanide mill.

KALGOORLIE, WESTERN AUSTRALIA

Progress Notes.—May Production.—Recent Accidents.—Ivanhoe Reserve.—Continuous Sluicing at the Oroya Brownhill.—Arsenical Concentrate at the Assciated Northern.

After eleven months dry weather all over the goldfields of this State, some very welcome rain has fallen, and the total to date is 3½ in. Such centres as Menzies, Norseman, Ora Banda, those out from Southern Cross, and up in the northwest, have been suffering for the want of rain for a good while, and many mines were shut down for the time. Now that the ponds are well filled, work is in full swing; and prospecting should be stimulated. Sulphide ore has been cut in the Gimlet South at Ora Banda, some forty miles from Kalgoorlie. The Associated Northern and Oroya Exploration companies have promising properties under option there. In appearance the sulphide resembles that of this centre, but not much has been opend up yet.

ASSOCIATED NORTHERN MINE.

The main shaft at the Lancefield is down 908 ft., and at the No. 7 level, the main drift is in 35 ft., with ore 90 in. assaying $6.96 per ton, while the south drift is in 29 ft., showing 70 in. worth $8.16 per ton. At the Youanme, worked by the Oroya Exploration Co., the lode at 300 ft. at various points is showing from 50 to 72 in., averaging $10 to $14 per ton. This is a good property and a 20-stamp battery is being erected. At Southern Cross, the Mountain Queen and Prince are showing well. At the former the mill is nearly completed. This consists of two Holman pneumatic stamps, and is the first instance of this type of mill in Western Australia. The East Pool & Agar mine in Cornwall has them at work, showing a marked increase in economy over the old Cornish battery it had working. If satisfactory at the Mountain Queen, the government may erect others at several small centres needing crushing facilities.

OROYA LINKS DUMP.

During May the gold yield from the State totaled $2,390,000, and $88,000 paid in dividends. Below are the yields from the chief producers.

Name.	Tonnage.	Yield.	Profit.	Dividend.
Associated	9,274	$68,900	$1,600	.....

*From old residue. †Loss.

There have been a number of accidents of late on the mines. At the Sons of Gwalia a skip, loaded with 9 men, rushed away down the 2500-ft. incline to the bottom of the main shaft. Three were killed, but as the rope was attached and the brake hard down on the drum, the result was not as bad as it might have been. The drum being out of gear was the cause. In the Boulder, a man was practically engulfed in the collapse of some filling. Also, in the same mine, a trammer fell to the 1800-ft. from the 1300-ft. Two were killed in the Eclipse mine of the Oroya Links, in knocking down some dangerous-looking roof. In the Ivanhoe mill, a shift foreman was electrocuted by catching hold of an electric-light wire.

It may be remembered that the Western Australian Government demanded extra payment on dividend duties from the mines, amounting to some $200,000, including past years. The companies pay income tax out of another fund, the shareholder getting his full dividend; but the Government argued that it should be paid out of the dividend only. After argument in the Supreme and Full Courts in Perth, the test case against the Horse Shoe for $26,000 went to the Privy Council, which decided in favor of the company, remarking that the act was very vague.

The Ivanhoe management publishes its reserves at 980,046 tons worth $10.68 per ton, and the consulting engineers, Bewick, Moreing & Co., place them at 1,008,464 tons at $10.80, distributed as follows:

East Lode, 690,243 tons at $10.46 per ton; Middle Lode, 211,801 tons at $11.10; New Lode, 87,271 tons at $10.90, and Boulder Lode 25,220 tons at $10.22 per ton. The total value is $11,040,000, taking the lowest estimate.

The water used during the month by the Mines' Water Trust amounted to 36,516,000 gal., or 1,178,722 gal. daily. The use of wood pipe is extending, as water rapidly corrodes iron and steel pipe, especially when hot. The power company here has just laid down a 6-in. main, and in the alterations to the main conduit of the water scheme, large wood bends are being fitted in. In the May number of the *Chamber of Mines Journal*, B. L. Gardner has a paper on 'Slime Settlement', dealing with the rate of flow and settlement in spitzkasten, and a method of accelerating the settling as at the Sons of Gwalia. The heap of old residue on the Oroya Brownhill, some 500,000 tons, has been all re-treated in the vacuum-plant of the Oroya Exploration Co. The plant will now be used in treating the fresh slime from the Oroya Links mill, which consists of 50 stamps, pans, Wilfley tables, tube-mills, bromo-cyaniding the slime, and roasting the concentrate. This is the first instance on the 'Golden Mile' of treating the current mill-slime in a vacuum-plant continuously. A good wash is expected, probably better than from the old material.

A lot of 200 tons of arsenical concentrate, with a 21% As. from the Transvaal mine, near Southern Cross, is to be treated at the Associated Northern mill this week. The whole plant will work on this ore and good opportunities will be afforded of watching any ill effect on solutions.

NEW YORK

The Copper Situation.—Doubt as to Actual Consumption.—Futility of Curtailment.—Progress at the Boulder.—Production at the Ray Con.—Eastern Share Market.

The figures of the Copper Producers' Association covering July output are serving to direct some attention to the copper situation. There are some interesting analyses of the figures covering the first six months of the year, and some intersting comments concerning the improvement of which so much was made when June figures showed a small decrease in accumulated stocks. One London analyst, writing of the gratifying increase in export demand from America, says: "The natural satisfaction is chastened by doubts as to whether the whole of the increased exports can be on account of legitimate consumers. Monthly exports of 31,900 tons are so much in excess of last year's monthly average of 26,870 tons, and the shipments of late months have been so substantial that even when Europe's record consumption is taken into account, one cannot altogether avoid the suspicion that invisible stocks are being piled up somewhere on this side." Shipments for the month of July are expected to show exports of 36,000 tons, which will possibly show a decrease in surplus of between 10,000,000 and 15,000,000 lb. If indeed it is true that copper shipped abroad is not going to consumers, but into storage, it is simply an effort of the controlling factors of the copper market to lift themselves over the fence by their own boot-straps that cannot be seriously defended except as a measure of rather desperate necessity which is likely to prove a boomerang. While it may be said that this thought has not been absent on this side of the water, the desire for improvement has been so strong and so universal, that none has seen fit to give it voice.

In all of the crusading against the trusts, the assaults upon combinations, none of the defenders of the corporations has thought to point to the huge economic waste entailed in the present status of the copper producers. If it is to be admitted that there is a valid argument in favor of the Steel Trust, for instance, it is to be found in the plight of the present copper producers, who are powerless to conserve their resources or protect their market. The recent quarterly reports of the Utah Copper and the Nevada Consolidated demonstrate the futility of any attempts at curtailment. Utah's output for the half-year is 15,766,523 lb., as against 15,583,640 lb. for the latter half of 1910 and 13,645,871 lb. for the first half of 1910. Copper costs were 8.02c. for the quarter. Calumet & Arizona, is another producer that is keeping output up to full capacity. The output for July was 4,394,000 lb., as against 3,656,000 lb. in June and 4,929,000 in July. The new smelter planned for the Calumet & Arizona is to cost about $1,500,000, and is expected to reduce costs materially below the present figure of 8c. On the present output and at the prevailing price, Calumet & Arizona is earning its dividend of $4 per share.

Pope Yeatman has just returned from Chile, where he has been superintending the construction work on the Braden Copper property. The first unit of the concentrator is just going into commission, and the entire concentrating-plant will consist of three units each of 1000 tons capacity. The hydro-electric power-plant is all completed save final touches; transmission lines are up and generators in position. Mr. Yeatman says that the most important feature of the Fortuna mine is the fact that the orebodies are unquestionably of primary origin, and may consequently be expected to persist in depth.

Progress is being made on the Ray Consolidated plant. The fourth unit of the concentrator has just gone into commission. This additional capacity will put Ray Consolidated on a basis of 4,400,000 lb. output per month. When the eight sections of the concentrator are completed and running up to the full capacity hoped for of 1250 tons per unit per day, the copper output will be 100,000,000 lb. per annum. Butte & Superior shareholders have had a long, hard pull, and by far the greater part have either actual or paper losses piled up against the investment at the present time. However, there are said to be some early betterments contemplated. A new process is to be used at the Basin Reduction works, which is said to be effecting a saving of 90%, as against 68% saved heretofore. In addition, the company plans to erect a new concentrator of a capacity of 500 tons daily on its own property. The management has been in consultation with D. C. Jackling and C. M. MacNeill of the Utah Copper Co., regarding the equipment necessary to make the new plant as complete and perfect as possible.

While the Eastern financial centres are undoubtedly learning to study specific properties and are beginning to realize that "the tape does not always tell the whole story", still the interest centres in markets and quotations. The prevailing stagnation has been the chief subject of comment for some months. Markets have been held remarkably firm in the face of the dullness, but there are signs of a break at hand. The latter part of the current week saw some remarkable liquidation, both on the floor of the New York Stock Exchange and in the mining shares on the outside market. The Porcupine issues especially came in for some heavy selling, and it would appear that the forced realizations following the fire are just beginning really to come into the market. The strain of the situation is beginning to tell, nerves are beginning to jangle, and, as one member was heard to say recently: "If the turn does not come soon there will be some Stock Exchange seats for sale at reduced prices." Porcupine is rebuilding, and in most instances the equipment destroyed is being replaced by larger and better plants, but so far as market interest is concerned, it appears plainly now that any general interest or any boom is to be postponed for a year, until some of the properties now developing begin to produce and pay dividends. The Mexican situation, the disturbed conditions, the unrest, and the frequent outbreaks have definitely postponed any contemplated new developments in that country, and, very naturally, have also limited market activities to selling on the part of the frightened holders.

General Mining News

ALASKA

The high-grade coalfields and copper and gold deposits in the region tributary to the Pacific seaboard of Alaska, which are being tapped by railroads, are being energetically explored by parties of the Geological Survey. D. C. Witherspoon's party is making topographic surveys, and another under F. H. Moffitt, assisted by Theodore Chapin, is making geologic surveys and studying the mineral resources of the Hanagita valley and Bremner river basin in the Copper river region. J. W. Bagley has completed a topographic base-map of the Valdez inlet mining district, and after surveying the Moose Pass district will map the Sunrise placer region. R. H. Sargent, with a party of five, is mapping the western part of Kenai peninsula.

In all, 14 parties, including about 50 men, are mapping and studying Alaska. One party under P. S. Smith, geologist, and C. E. Griffith, topographer, is exploring unsurveyed and almost unknown land along the Noatak river, northwestern Alaska. It will go up Alatna river in canoes in the hope of finding at the head a pass to the head of the Noatak, so as to descend the latter to the Arctic ocean at Kotzebue sound. A. C. Maddren, working in conjunction with a party of the International Boundary Commission, is studying the geology and mineral resources of northeastern Alaska, north of Porcupine river. C. E. Ellsworth in the Fairbanks and Birch creek districts, and E. A. Porter in the Forty-Mile district are investigating water-supply for placer mining in the Yukon-Tanana region. L. M. Prindle and H. M. Eakin are leading parties in the same region for reconnaissance mapping and studying the mineral resources. G. C. Martin is studying the coal resources of Kenai peninsula and later will visit the Katalla oilfield. B. L. Johnson is studying the lode and placer deposits of the northern part of Kenai peninsula, where important developments have been made. The Yentna placer district is about 150 miles north of the head of Cook inlet. S. R. Capps is conducting a study of its geology and minerals.

MAP OF ALASKA.

A. H. Brooks, geologist in charge of the Alaska surveys and investigations, will sail from Seattle, August 15, for Prince William Sound. He will visit the lower Copper river region, the Valdez inlet mining district, and the Kenai peninsula.

Eleven men were caught in a cave-in in the Chitina tunnel of the Copper River & Northwestern railroad. W. A. O'Neil, foreman, and John Sethers were killed. A third is missing. The ten were promptly dug out.

JUNEAU

J. E. Clark has discovered a vein rich in free gold on the east fork of the Skagway river, near Whistler's gulch. A claim has been recorded.

THE TANANA

In the fiscal year commenced in July 1910, over 240 quartz claims have been recorded at Fairbanks, say Alaskan papers dated last June. The entire Fairbanks district and some adjoining territory are represented.

A 4-stamp mill of 25 tons capacity has been shipped to the Chandlar district for the company headed by S. J. Marsh, United States Commissioner in the Chandlar district. It is to be in operation by January 1. The company has 13,000 tons of $40 ore blocked out, according to press reports. The vein averages 6 ft. wide.

ARIZONA

GILA COUNTY

The Burch rolls, used in No. 4 unit of the Miami Copper Co.'s concentrator at Miami, have proved unsatisfactory for that kind of ore, and Chilean mills will be used in No. 5 and 6 units, which will be started as soon as possible. The Burch rolls in No. 4 will be retained for further experiments. Chilean mills are used in No. 1, 2, and 3 units. Before the end of the year, it is reported, the Miami mill should be running with all six units in operation. The capacity of the mill is to be 3000 tons per day. The concentrate is being shipped under contract to the Greene-Cananea smelter, and the product is again taken over the Mexican boundary to the Raritan refinery of the International Smelting & Refining Co. Sales, according to report, are being handled by the United Metals Co., a subsidiary of the Amalgamated Copper Co. Production has been under way only a short time, and only a small amount of copper has reached the market.

The Black Warrior Development Co., promoted by Smith & Hovland, has shut down the Warrior mine. It is rumored that the mine will be abandoned and will revert to its former owners. Reports state that its production was sufficient to more than pay expenses during the two years ownership by the present company.

GREENLEE COUNTY

At the Twin Peaks mine a rich vein of sulphides has been found at the 100-ft. level.

MARICOPA COUNTY

The Big Blue M. Co. will start active development work early this fall. A Bryant mill with tables, and a pump for unwatering have been ordered. J. A. Caskey is superintendent for the company.

YAVAPAI COUNTY

Eastern capitalists, headed by W. E. Sharps, of Philadelphia, have acquired the Yarnell gold mine, six miles from Congress Junction. Press reports state that over 200,000 tons of $6 ore is blocked out. A 100-stamp mill is to be built and a cyanide plant will be added later. The ore is a white quartz. The mine is five miles from the old Congress mine.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—It is reported that the July clean-up of the Kennedy mine amounted to $100,000. The increase was due to the milling of the rich ore deposit recently opened on the 2800-ft. level. One hundred stamps are constantly in action. At the Bunker Hill during the past six months the ore treated averaged slightly less than $5 per ton, as special attention was paid to milling low-grade quartz. The company continued to disburse its regular monthly dividends of 5c. per share, and it is possible that this rate will be increased before the close of 1911. On the 1950-ft. level the vein is reported 90 ft. wide in places.

Arrangements for the vigorous operation of the Valparaiso are under way. The new 500-hp. electric hoist has been placed in position at the Argonaut, and operation at full capacity is about to be resumed. A rumor is in circulation that the celebrated Eureka mine, owned by Mrs. Hetty Green, has passed into the hands of a strong company. The Eureka was formerly the premier producer of the Mother Lode.

Jackson, August 4.

BUTTE COUNTY

(Special Correspondence.)—Lava Beds dredge No. 3 of the Oro Water, Light & Power Co. was put out of commission while working near Oroville, August 6, by a strange accident. The [illegible] point of a [illegible] caused by pinching [illegible] down on the dredge when the [illegible] gave way and [illegible] the working [illegible] back [illegible] the end of the dredge. The machinery was not injured. The dredge, which has been [illegible] to have been [illegible], in any case.

Oroville, August 8.

Nevada County

(Special Correspondence.)—The Gaston Mining Co. has been crippled temporarily during the repair of the flume and ditch of the Northern Water & Power Co. The heavy snows and slides of last winter damaged the flume to the extent that an order was placed with the Gaston sawmill for 80,000 ft. of lumber, which is now being cut. The mine is running with a slightly reduced force, and the 40-stamp mill is dropping 30 stamps. It is expected that both the mine and mill will be shut down for about two weeks while the flume is out. About 75 men are employed at the property, which is one of the largest in northern California. Claude Ferguson is superintendent.

Gaston, August 1.

Shasta County

The Monarch mine, on the west side of Clear creek, and Paige's mine, on the east side, were menaced this week by forest fires. The flames came within 50 ft. of the Mt. Shasta mine, which was saved only after hours of work by every employee. Several prospectors' cabins were burned.

Sierra County

(Special Correspondence.)—A. B. Call, of Pasadena, has bonded the Grizzly ridge claims owned by Mark Alling, a mining engineer of Downieville. The property consists of four 160-acre claims covering $2\frac{1}{2}$ miles of ancient lava-capped channel, of the Neocene age, never yet bottomed. The channel contains a white and blue quartz wash carrying gold along its course, and where tributaries have been followed into the ridge. Rich ore is expected when the bottom is tapped. The channel is covered with a deep flow of pipe-clay, over which lies an ancient andesite capping. The property is on the same ridge as the Delhi mine, Nevada county, and as the nature of the wash is similar to that of the Bald Mountain mine, eight miles northeast, across the river, it is thought it may be the same channel, although it formerly has been thought that the Bald Mountain had crossed from Moore's Flat to North Bloomfield. The ridge is heavily timbered, and a wagon-road lies along the property.

Downieville, August 7.

(Special Correspondence.)—A large bed of rich gravel has been uncovered at the Haskell Peak mine, in which August Johnson states that a second channel was found under a stratum of pipe-clay. The first channel, which the company has been developing for the past two seasons, is known to have yielded big dividends. The work of hauling the timber necessary for the sluice-boxes soon will be started. The company expects to be in full blast this summer.

Haskell Peak, July 25.

The first deep mining in the Alleghany district soon will be started as the result of the sale of the Red Star and Tightner mines to San Francisco investors. The Red Star vein is considered to be a continuation of the Tightner vein. The construction of a 10-stamp mill has been commenced at the Tightner and should be done in 45 days. H. L. Johnson formerly owned the properties.

George Scarfe, Jr., superintendent of the Middle Yuba Hydro-Electric Co., is in San Francisco to purchase motors to operate a new air-compressor and other machinery soon to be put in at the Omega mine. The Middle Yuba company will furnish power for the mine. Much interest is being shown in the Red Star mine's electric equipment.

Tuolumne County

(Special Correspondence.)—The company which has been exploiting the gravel deposits near Columbia with a Keystone drill has incorporated under the name of Columbia Basin Development Co., the incorporators being J. B. Watson, F. S. Duncan, and James Sam, all of San Francisco. Gold-bearing gravel was recently penetrated with the drill, and a three-compartment shaft has been started. It is planned to drive a long adit from the Stanislaus river to drain the basin in which the property is situated. The company expects the arrival soon of two large boilers and two Cornish pumps.

The Star King mine has been sold to A. H. Wagner and R. C. Kennedy, of San Francisco. A mill will be erected to replace the one destroyed by fire several years ago and a hoist and other machinery will be built at once. Mr. Wagner will personally direct all work. The machinery for the Gold Ship gravel mines, near Groveland, has begun to arrive and active mining operations will be commenced soon. Porterville capitalists have begun development of the If I Can gravel mines, one mile above O'Byrnes ferry, on the Stanislaus river, and it is said that at least 30 men will soon be employed. The property comprises several hundred acres and is developed by two adits which have reached gold-bearing gravel. The Empire mine, owned and operated by L. H. Jansen, is being extensively developed. The property is opened by a shaft 200 ft. deep, from which several drifts have been driven, exposing a vein of good ore 4 to 5 ft. wide.

A power-drill has been purchased for the Hardtack and Hunter mines, operated by Messrs. Redding and Gledhill, and other machinery will soon be ordered. The Uncle Sam mine, at Arastraville, is being reopened for inspection by prospective purchasers. A mill test of 10 tons of ore taken out in the development of the Gem mine, near Confidence, returned 24 oz. gold. Assays show the sulphide to be of a high grade. The unwatering of the Juniper mine is almost finished and development work will soon be in progress. Only a few men are employed at the Soulsby and the announcement of the complete suspension of operations is daily expected. The resumption of operations at the Manganate mine, near Jamestown, is contemplated for an early date.

Tuolumne, August 6.

Yuba County

Dredge No. 13, the largest gold dredge in the world, has been formally put in operation on the Yuba river, near Hammonton, by the Yuba Con. Gold Fields. W. P. Hammon, president, and other officers of the company and a number of their friends were present when the electric current was turned on. The dredge was started on Friday, August 4.

COLORADO

Gilpin County

The Rexall G. M. Co. has bought most of the principal producing lode and placer mines in the northern part of this county, including the well known Perigo and Gold Dirt placer properties. It is reported that the former owners, Hal Sayre, E. W. Williams, James E. Lightborne, and Thomas H. Potter, will become stockholders in the Rexall company and that Mr. Williams will be elected to the board of directors. These men gradually had acquired these properties through advancing money to prospectors, but comparatively little development work has been done. The Rexall company will place dredges and do extensive development work. Charles Knight is general manager for the company. The property consists of 2500 acres of placer ground and 700 acres of lode claims, including the Rollins and Pactolus placer mines, water-rights on South Boulder creek, and the townsite of Rollinsville.

Saguache County

(Special Correspondence.)—A new Colorado record for the first month's use of machine drills was established in June at the Rawley M. Co.'s mine near Bonanza. The distance was 380 ft., against the former record of 302 ft., made by J. A. McIlwer on the Laramie-Poudre adit in January 1910. W. C. Russell is manager for the Rawley M. Co. In July the Rawley company's 6250 by 7 by 8-ft. drainage and development adit was advanced 414.23

ft. The adit on August 1 had been driven 905.23 ft. Two shifts worked 29½ days in July. The No. 8 Leyner Water drill is being used.

Bonanza, August 6.

San Juan County

Press reports state the Little Maud mine, Maggie gulch, has been taken over under lease and option by the Danforth Investment Co. E. J. C. Riley, of Cripple Creek, representing the Danforth company, made the deal.

San Miguel County

The Ophir Gold Mines, Milling & Power Co., which last year acquired the old Suffolk properties at Ophir is planning to mill all of the ore from the workings, which for years were tied up in litigation. A tram will be built from the mill to the No. 5 Suffolk level and to the Lilly, a new opening, from which all of the levels will be worked. New buildings have been erected at No. 5 level and a large force of underground workers can be cared for. With the tramway, aside from the expense of removing the ore, the treatment cost will be but 80c. per ton, a saving of about $3 over the days when lessees operated the property. The company has valuable water-rights which make 250 hp. available throughout the year. The whole hill where the property is situated is said to be a network of gold-bearing fissure veins, some low grade and some high grade, running $40 to $50 per ton. George B. Pickett is general manager.

PERIGO MILL.

The Alta mill, recently enlarged by 10 stamps, will be increased 10 more stamps shortly. The increased output will be about 45 cars per month.

Teller County

The Index shaft at Cripple Creek, on the south point of Gold hill, will be sunk to 1000 ft. The hoist has been overhauled.

IDAHO

The production of gold in Idaho this year will be 25% heavier than the production of last year, says Joseph Pinkham, who is in charge of the United States assay office at Boise. An abundant supply of water has lengthened the placer season, many new claims have been developed, and several old mines have been reopened and placed on a paying basis. The Gold Hill mine at Quartzburg, closed for 30 years, has been opened by Mrs. M. Hall, of Boston. The Boise basin placer mines will produce more gold this season than in many years.

Idaho County

Humboldt Quartz & Placer M. & M. Co. has been organized in Spokane by F. E. Garman and his associates to develop thirteen 20-acre placer claims near Marshall lake. Fifty thousand dollars is to be expended, if necessary, in equipping the property and buying 10 other claims in the district, which is between the famous Florence and Warren camps. J. J. Moak, superintendent and general manager, announces that two giants and 1000 ft. of steel pipe will be used, which will give a 200-ft. head of water from Grouse and California creeks. The prospect assays show average values of $2.75 per yard, according to report.

Shoshone County

The Granite-Allie M. Co., near Murray, will erect a 100-ton mill, in a building large enough for a 300-ton mill. A sawmill will be built to furnish lumber for a flume. The shaft is down 220 ft. in good ore, according to report.

The Four Ledge M. Co.'s silver-lead properties, comprising 15 claims, four miles west of Wallace, have been acquired by the Burlington M. Co., of Spokane, headed by Ben. E. Hewey. A water-power plant will be constructed.

MONTANA

Lincoln County

(Special Correspondence.)—The Cornet Placer M. Co., operating on Libby creek, has closed to allow a clean-up of the sluice-boxes. The Libby Placer M. Co. is constructing a large hydraulic plant. The latter company also has closed for a clean-up of the sluice-boxes.

J. M. Roberts and Louis Hale believe they have found the district in which Lincoln county's lost gold mine is situated. A 15-ft. vein of coal was reported in the northern part of the county by three gold prospectors in the early sixties.

Libby, August 2.

(Special Correspondence.)—The Snowshoe mine, which has been in operation for the past three months, since its purchase by the Pacific Coast Smelting, Refining & Mining Co., is to begin shipping ore to the smelter at once. Although the concentrator has been running for over two months, no ore as yet has been shipped. There is now about 2000 tons of concentrate on hand. The ore will be hauled by teams for eight miles, to the Libby Lumber Co.'s logging railroad, where it will be loaded on Great Northern cars. E. H. Wilson, consulting engineer for the company that is operating the mine, is planning an adit to the vein on the opposite side of the mountain from the present workings to obtain a depth of 1000 ft. This step is possible through the purchase of claims adjoining the mine. Another air-compressor will be added. The company is employing about 100 men.

Libby, August 3.

(Special Correspondence.)—The steam-drill which was taken to the placer ground south of Libby recently is now in operation and holes are being sunk on the land for testing the ground. It will take several months to prospect all the ground, as the machine can only drill about 10 ft. per day. C. B. Campbell, of Colorado Springs, Colorado, is back of the enterprise, and has been on hand this week to watch the operations. There is about 1000 acres of land on Libby creek that is thought to be suitable for dredging. Mr. Campbell has an option on about half of this. G. F. Hinton, a placer mining expert, is in charge.

Libby, July 30.

NEVADA

Clark County

The Yellow Pine mill will soon be in operation. The fourteen-mile narrow-gauge railroad from Jean, on the Salt Lake route, to the mine is nearly completed. An electro-gasoline engine will be used. The ore-shoot has been followed down to the 400-ft. level and appears to be larger in the lower levels. A power-plant will be constructed at the mine. J. F. Kent is manager.

Esmeralda County

The Goldfield Con. M. Co. on July 31 mailed checks for a dividend of 50c. per share on all outstanding shares. The approximate figures for July show a net profit of $650,000, against $679,537.16 for June and $796,151.64 for May.

Humboldt County

Press reports state that slabs of almost pure gold are being taken out of the Adamson-Turner mine at Rexall, the Winnemucca mountain camp. The reported ore comes from about the 100-ft. level. Some of the ore has been screened and sacked, and it is believed will assay about $1000 per ton.

Lander County

(Special Correspondence.)—The Austin Manhattan Con. M. Co. announces that the developments at its mines, and the operation of its mill have been so satisfactory that additional capital will be raised to conduct operations on a larger scale. The plans include the erection of a 150-ton mill, with cyanide departments. The manager recently stated that only bullion will be shipped, and that the concentrate will be treated on the ground. The holdings comprise the greater part of the Reese river mining district. At present a small plant is treating ore, employing the Huff Electrostatic process. Maricopa Mines Co. is erecting a 100-ton mill on the Patriot, which has been leased from the Austin Manhattan for an extended period. The Kingston mine and mill has been taken under lease and bond by John C. Charles of San Francisco and F. C. Hazzard of Los Angeles. The purchase price is understood to be $200,000. The property is 25 miles south of Austin.

Austin, Aug. 3.

Lyon County

The Rea, Baruch and Erickson property, consisting of 50 acres near Dayton, a mile and a half above the Logan & Hully mines, has been bonded by H. C. Cutler for Eastern capitalists. The shaft will be unwatered to the 500-ft. level. A 300-ton mill is on the place. Mr. Cutler, who formerly was consulting engineer to Nixon & Wingfield, will be manager.

The new 800-ton smelter in Mason valley is expected to blow in some time in November. The 200-ft. stack is completed and the dust chamber is being constructed. All structural steel for the sampling mill is on hand and much of the blast-furnace building steel has been received. The equipment for the 6600-ft. tramway to the Copper Belt railroad is ready. It will have a capacity of 100 tons per hour. From the 400-ft. level raises are being driven to the surface to obtain the limestone needed for fluxing.

Nye County

The Manhattan Big Four M. Co. has declared its second dividend of 2c. on 762,000 shares outstanding. The payment will be made August 15. The first dividend, also 2c., was paid May 5. Of the three leases, the Poak-Steen-Cicola has produced $225,000 in the last eight months.

At the War Eagle claims preparations are being made for sinking a permanent working shaft. J. McCummon is superintendent for Malcolm L. Macdonald, who has a lease from the Humphrey brothers.

J. C. Charles, of San Francisco, and F. C. Hazzard, of Los Angeles, have bought the old Kingston mine, in Kingston canyon, Smoky valley. Harry Green and A. D. Sly have leased the Union No. 2 property and will install a whim shortly. It is reported that some Philadelphia capitalists, headed by John Whilldin, are planning to buy the Priest mill. R. H. Toll, a Denver mining engineer, is to make a report on the property. The Happy Day claim, near Central, formerly owned by the Goldfield & Bald Mountain Con. M. Co., was bought at a sheriff's sale by Martin Bartholino. Work shortly will be resumed on the Hoosier claims, at East Manhattan, near Mineral hill. The shaft, 300 ft. deep, has passed through encouraging ore and will be continued to water-level. J. B. Houppert, vice-president, is at Manhattan.

Storey County

The Mexican M. Co., after nearly 50 years of existence, has declared its first dividend, which is the first dividend since the Ophir's in 1908, on the Comstock. The disbursement on the 201,600 shares will call for $20,160, and will leave on hand about $30,000 for August expenses. With the mill, now under construction, it is believed that dividends can be maintained next year. The Mexican M. Co. has received a report from the smelter showing a net yield for July of $44,860.30.

The official weekly reports of the superintendents at the north end show a large ore extraction in July. There was a substantial increase in the output of the Ophir and a decrease at the Mexican. The former reports show a total of 1466 mine-cars hoisted, giving a gross assay value of $51,429.17, more than $12,000 in excess of June's output. At the Mexican, 1810 cars was hoisted, giving a gross assay value of $71,776.08. The Mexican was shut down for more than a week. Other producers in the Comstock district include the Union Con., Con. Virginia, Comstock Phoenix, Monte Cristo, Cosmopolitan, Chollar, Potosi, Gould & Curry, Justice, and Crown Point.

White Pine County

The Nevada Con. Copper Co., in its second quarterly report for 1911, announces a deficit of $1130, incurred after payment of dividends amounting to $749,389 and charging off $136,991 for depreciation. Net earnings were $886,266. The production was 15,677,065 lb., against 15,893,743 for the first quarter, and 15,698,595 for the last quarter of 1910. The ore treated averaged 1.59%, the lowest grade yet milled. The average was lowered through the treatment of a large amount of ore of low grade, yet too valuable to be thrown away. The deficit was caused through reducing the figure at which stocks were carried, and $23,826 was deducted from the former metal price reserve, $46,629. The first basic-lined converter was scheduled to go into operation August 1. The undivided profits are $2,159,310, and the surplus $9,056,153.

OREGON

Baker County

The Virtue M. Dev. Co., eight miles east of Baker, is changing to electric power, and is remodeling the mill. A cyanide plant will be added. At present the mill is not operating. Power will be delivered in a few months by the Eagle River Electric Power Co., whose plant is now under construction. The Virtue M. Dev. Co. property includes eight former holdings. J. K. Romig is manager.

Press reports state that work will be commenced immediately on the big Keystone company's dredge near Sumpter. The dredge will be a Bucyrus and is to have a capacity of 7000 cu. yd. of gravel per day. Electric power will be used, furnished by the Oregon Light & Power Co. from its substation at Bourne. R. W. Derby has charge for the Keystone company.

W. H. Turner, of Spokane, has been elected president of the Humboldt Con. G. M. Co., which has taken over the holdings of the Humboldt G. M. Co. in the Mormon basin near Baker. The vein has been traced for more than 5000 ft. within the company's ground, and 600 ft. of drifts shows ore for nearly the entire distance, ranging from 2 to 45 ft. in width. A large quantity of ore has been taken from the property by Colt Brothers, the former owners, but there still remains more than $250,000 worth of ore in sight. The shaft will be extended 100 feet.

UTAH

Salt Lake County

The Utah Copper Co., in its report for the second quarter of 1911, April, May, and June, gives its gross production for that period as 24,469,812 lb. copper. May's production was the highest, 8,391,879 lb. The average monthly production was 8,156,604 lb., against an average of 7,098,903 for the first quarter of 1911, and an average of 7,563,940 lb. for the last two quarters of 1910. The average cost per pound during the quarter, after allowance for smelter deductions and without crediting miscellaneous income, was 8.02c., against 8.434c. for the first quarter. The ore treated amounted to 1,060,414 tons, against 981,104 tons for the first quarter. The copper content was 1.6332% against 1.5509% for the first quarter. The net with Nevada Con. dividend, was $1,366,944.17 for the quarter, of which $1,177,011.75 was paid in dividends, leaving a surplus for the quarter of $189,932.42, computed on a basis of 12¼c. per pound of copper. Average extraction was 70.64%. From Utah and Boston groups 1,395,504 cu. yd. of capping was removed, as compared with 957,149 during the first quarter. The mine will be put in shape for winter work without stripping under poor weather conditions. Track has been laid across Dry Fork bridge on the Bingham & Garfield railroad, and track is to be laid to the Garfield smelter early in August. Equipment is expected to arrive in time for operation in August.

WASHINGTON

Okanogan County

The Granby Consolidated Mining, Smelting & Power Co. bonded seven claims on Copper mountain, Myers Creek district, last February, and has been prospecting them with a diamond-drill. One hole cut 86 ft. of rich ore, a second one 56 ft., and another ran 40 ft. through iron sulphide. Since then the company has sent in experts who have examined other claims nearby and are negotiating for them. Among them is the Battle Axe, from which ore assaying $60 to $80 per ton has been shipped. These properties are six miles northeast from Chesaw.

Pend Oreille County

Metaline Oriole M. Co., headed by Fred N. Davis, has just shipped its first consignment of two cars of high-grade ore from Metaline Falls to the United States Zinc Co.'s smelter at Blende, Colorado. Six cars of ore is blocked out. Plans have been approved for sinking a 250-ft. shaft during the coming fall and winter. The adit, now in 586 ft., was driven in 72 days at a cost of $6.43 per foot. In addition, there is some open-cut work and a short adit on the vein, where several tons of good ore has been taken out. No. 2 adit is in 225 ft. and has reached a depth of 100 feet.

CANADA

British Columbia

(Special Correspondence.)—The Inland Empire M. & M. Co., Ltd., at Paulson, is putting in a 10-stamp gold-mill. D. G. Daires, mining engineer, is in charge of the work.

Paulson, July 21.

Work at the Portland Canal M. Co.'s concentrator has been resumed. The plant has been enlarged to treat 80 tons of ore per day. The mill equipment consists of 7 Wilfley tables, an Overstrom table, 2 Frue vanners, 2 four-compartment 5-mm. jigs, and 2 four-compartment 3-mm. jigs. The whole plant is driven by water power.

Ore from the latest discovery on the Simpson claim, Salmon-Bear river, brought to Stewart by O. B. Bush, assayed $53.60 in gold and $510.64 in silver.

E. A. Bradley and associates are making extensive tests on Big Bend, French creek, preparatory to developing the placer district there on a large scale.

Ontario

(Special Correspondence.)—The Porcupine boom has resulted in a considerable revival of interest in gold mining in other parts of the province, more particularly in the Lake of the Woods district, where several mines which had for many years been closed down are now being worked. The Ophir, now principally owned by Charles Fishback, Chicago, is being operated with good prospects of success by a force under James Morton as superintendent. The shaft has been put down to the 100-ft. level, and some driving undertaken. The vein was found to widen to 9 ft. at depth and good ore is being taken out. At the Mikado, formerly a producer to the extent of about $500,000, where operations were resumed last fall, large orebodies have been found and 15,000 tons blocked out. Operations have been slackened latterly because of the refractory character of the ore, owing to its bismuth content, which will necessitate the building of a cyanide plant to prevent heavy loss in extraction.

A copper property near Kenora is being worked by Mr. Scovil and Frank Moore. A shaft is being put down to 100 ft. It is claimed that samples of ore taken from the 40-ft. level assay 27 lb. of copper per ton. Active work is being done at the St. Anthony gold mine in the Sturgeon Lake district, of which J. C. Houston is in charge. A new vein has been discovered running about 20 ft. in width, which has been traced for 300 ft. A winze put down 75 ft. from the 100-ft. level shows good ore all the way. The manager estimates the ore in sight at $500,000.

In order to avert the danger of a coal famine in the West this winter, owing to the protracted strike of the coal miners in British Columbia, the Canadian Government has by order-in-council remitted the duty on coal imported into Canada at points west of Sault Ste. Marie for consumption in British Columbia, Alberta, Saskatchewan, and Manitoba. This goes into effect August 7, unless the parties to the strike effect a settlement and resume operations before that date. The railways are also reducing freight rates on coal from Port Arthur and Fort William to western points, and it is anticipated that large supplies will be brought in from the United States.

Toronto, August 4.

Three bars of bullion recently were shipped from the Cobalt Lake mine to the Toronto office. The bars in the aggregate weighed 149.5 oz.

Yukon

The McKinnon brothers and Messrs. Clark and Fotheringill have leased the stamp-mill formerly belonging to Mr. Bennett and associates of Dawson, and have commenced crushing ore from the Indian river conglomerate deposit, which they believe will become another Rand.

MEXICO

Chihuahua

A rich discovery of silver ore was made recently at the Esmeralda mine, owned by the Esmeralda-Parral M. Co. A large quantity of ore running from 5 to 10 kg. silver per ton is being sacked. The ore was found on the fifth level south. Wade Armstrong is manager.

Confidence is growing in the Parral district, according to press reports. All of the old properties have resumed, and the district is remarkably free from strikes. To avoid any possible trouble, however, several new properties will not open before the elections in October.

The La Republica mine during June crushed 1051 tons of ore. The proudction was ₱78,656.76; operating charges, ₱52,393.10; and construction and equipment charges, ₱7188.74. J. Gordon Hardy, of El Paso, is consulting engineer.

Sonora

The electric hoist at the Calumet & Sonora mine at Cananea has just been completed. Electricity is obtained from the Cananea Con. Copper Company.

Bostwick and Dickson, owners of the Washington mine, near Huepac, are planning to organize a company to develop this copper mine. About 250,000 tons of ore is blocked out, which it is believed will run from 3 to 5% copper.

The Transvaal Copper Co. will build a concentrator at Cumpas and a narrow-gauge railroad from its mines to Cumpas, a distance of 200 miles. The work will be done within a year. O. C. Rasch is now at the property. The company owns 1966 acres of mining land, a 50-acre smelter site at Cumpas, and an interest in the San Nicolas-Tolentino ranch of 26,000 acres. The property includes the Cobre Rico, Transvaal, Buckeye, San Nicolas, Ultima Chanza, Virginia, and Guadalupe claims.

The El Tajo M. Co. is planning to develop other silver properties in the vicinity of the San Geronimo mine, which it operates.

The Mexican Metals Co. has allowed its properties in the Magdalena district to revert to the former owners, its parent company, the Dominion Syndicate. The Mexican Metals Co. now owns only the Arizpe Mining Co., later reorganized as the Arizpe Mines Co., and still later merged with the Mexican Metals, whose properties consist of 27,000 pertenencias, including the Alacran, Reydel Cobre, Palo Seco, Manhattan, and other holdings.

The Zambona M. Co. has added 10 more stamps and a tube-mill to its plant at Minas Nuevas. The Mauchacho Grande M. Co. is developing claims aggregating a mile long and a half-mile wide at Matopaco. Several veins of silver ore varying greatly in value traverse the property, which is in the Alamos district.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS

COAL MINING CORPORATION—DUTY TO SHOW INCORPORATION

The statute of Kentucky requires every corporation to place on its principal place of business its name and under it the word 'Incorporated.' Under this statute a coal mining corporation operating a mine in one county and maintaining a business office in another county maintains two places of business, within the meaning of the statute, and must place its name with the word 'Incorporated' at both places where its business is so carried on.

Commonwealth v. Nebo Consolidated Coal & Coke Co., (Kentucky) 134 Southwestern, 221. January 1911.

LOCATION OF MINING CLAIM—TRUST AGREEMENT AND STATUTE OF FRAUDS

It was orally agreed between several persons that one should explore the public domain and discover and locate mining claims for their joint benefit. Pursuant to such agreement, any claims located by one, either in his own name, or in the name of another, inures to the benefit of all, and the one in whom the legal title vests holds it in trust for all interested in the joint enterprise. And such an agreement based on a valuable consideration is not within the statute of frauds.

Hardin v. Hardin, (South Dakota) 129 Northwestern, 108. December 1910.

LIABILITY FOR INJURY TO BOY IN COAL MINE

The violation of the statute prohibiting the employment of a boy under 14 years of age in a coal mine may be rightly considered as the proximate cause of any injury which is the natural, probable, and anticipated consequence of such violation; but the employer is only liable for injuries against which the statute is intended to guard. Where the employment is thus unlawful, the boy under 14 years of age cannot be held to have assumed the risks incident thereto, including the risk of injury by a fellow-servant. But any contributory negligence on the part of such a boy injured in the unlawful employment is available to the employer as a defense, unless it be such that must reasonably be anticipated as a probable consequence of the violation of the statute. The fact that the boy misrepresented his age will not alone preclude him from recovering in an action for damages caused by violation of the statute.

Norman v. Virginia-Pocahontas Coal Co., (West Virginia) 69 Southeastern, 857. December 1910.

Burke v. Big Sandy Coal & Coke Co., (West Virginia) 69 Southeastern, 992. January 1911.

LIABILITY FOR DEATH OF MINER—EVIDENCE

In an action for the death of a coal miner, alleged to have been caused by rock falling from the roof of the mine, where the mine-owner was charged with having negligently failed to have the room, wherein the deceased was working, examined by the mine examiner and marked with chalk as of the date, there was a conversation between two mine inspectors about two hours after the accident, in which one asked the other if he had examined the room the night before and where he placed his mark, and being told where said it was not there then, to which the other replied "No." This was held to be a mere narrative of a completed transaction and not admissible as part of the *res gestae*. In such a case any error in permitting a witness to answer questions as to the proper practice in coal mining, as to whether it was possible to tell when a large untimbered rock was going to fall, is regarded as harmless, where the jury could not have understood that it was the duty of the mine examiner to remove the rock, and where it was self-evident that the precise time when such a rock would fall could not be determined.

Belskis v. Dering Coal Co., (Illinois) 92 Northeastern, 575.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

A STUDY OF THE BLAST FURNACE. By the Harbison-Walker Refractories Co., Pittsburg, Pa., 1911. 105 pp., ill. For sale by the *Mining and Scientific Press*. Price $1.25.

This little volume is a companion volume to 'A Study of the Open Hearth Furnace' and is an equally striking example of the art of book making. In recent years we have learned the fallacy of the pioneer idea that fine dress is an evidence of worthlessness, and these handbooks, bound in leather, with gilt edges, and beautifully printed on double-calendered paper, are a treat to the lover of good workmanship. The care with which the plates have been executed makes them particularly valuable. The book is not intended for a steel metallurgist, but its brief and comprehensive outline of blast furnace practice will be interesting, valuable, and useful to the many who desire only a brief discussion of this large subject.

METALLURGY OF TIN. By Henry Louis. Pp. 136; ill. McGraw Hill Book Co., New York, 1911. For sale by the *Mining and Scientific Press*. Price $2.

This little book is a revised and enlarged reprint of the article contributed by Mr. Louis to Vol. V of the *Mineral Industry*, 1896. A feature of the work is the large amount of space devoted to the description of native methods practised in the Straits Settlements and neighboring districts. It is only within comparatively recent years that descriptions of such methods of work have appeared in the journals of technical societies, and Mr. Louis has done good service in gathering together and amplifying them from his own experience. The volume concludes with a chapter on the utilization of tin waste and scrap. The metallurgy of tin is of interest to but rather a narrow circle, but its members will welcome this concise and lucid description of the subject.

STRAIGHT-LINE ENGINEERING DIAGRAMS. By Manifold & Poole. Cloth. Pocket size. Technical Pub. Co., San Francisco, 1911. For sale by the *Mining and Scientific Press*. Price $3.

This little book contains diagrams by which it is possible easily and quickly to solve a large number of engineering problems that constantly arise in the field. No calculations or drawings are necessary, and it is but the work of a moment to compute approximate solutions. Among the problems solvable by its use are, bearing power of piles; depth of keystone in masonry arches; strength of concrete of different porportions; economical percentage of steel in reinforced concrete; strength of beams; voltage losses; deflection for copper and aluminum wire with various spans and temperatures; relations of kw., hp., voltage, amperage, etc.; size of wire for power transmission; comparative cost of power; hoisting and haulage problems; flow of water in pipes and canals; water measurements; stadia measurements; gearing and shafting problems. The book will prove a great convenience to field men everywhere.

Recent Publications

ENGINEER MOUNTAIN FOLIO. By Whitman Cross and assistants. U. S. Geol. Surv., Geologic Atlas, Folio 171, Field Edition, 1910. The engineer mountain quadrangle lies south of the Telluride and east of the Rico in Colorado. The district is an interesting one from the point of view of general geology, but ore deposits of large value have not yet been found within its limits. The 'Field Edition' of the folio is published in pamphlet form, 9½ by 6 inches, with flexible back, and maps folded in pocket. The library edition is in the old style of flat folios, 17 by 21 inches.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. C. Pickering is in London.

H. E. Bush was in San Francisco.

J. Power Hutchins is in London.

Hennen Jennings is in San Francisco.

R. A. F. Penrose, Jr., is at Los Angeles.

J. Morgan Clements is in San Francisco.

Louis J. Mayreis has returned from London.

Norman C. Stines is at Vladivostok, Siberia.

J. F. Brandes is now living in San Francisco.

Gelasio Caetani has gone to Telluride, Colorado.

Edmund Juessen will go to Pittsburg next week.

Percy E. Barbour was in San Francisco Thursday.

Courtenay De Kalb was in San Francisco this week.

A. H. Keller is leaving for Colombia, South America.

Carl F. Dietz is in Maryland on professional business.

F. G. Clapp has left Pittsburg for field work in West Virginia.

Charles P. Richmond is at San Miguel, Salvador, Central America.

Fred L. Lowell has returned from a wedding trip to Sitka, Alaska.

Alden H. Brown has been in San Francisco and has gone to Nevada.

A. A. Hassan is at Cobalt, from which point he will make exploration trips.

Arthur J. Hoskin is returning from a short business trip to the East.

C. T. Durell is making a tour through Australia before returning to the United States.

Dyke V. Keedy is in Maine, examining some mining property for New York people.

Joseph H. Playter has returned from Mexico to the management of Nevada Crown Mines, Golconda, Nevada.

Howland Bancroft has left Lima, Peru, for La Paz, Bolivia, which will be his headquarters for the next six months.

C. Frederick Sherwood has been in San Francisco and has gone to New York *en route* to Buena Ventura, Colombia, South America.

Carl L. Allen, of Allen & Colburn, Denver, has returned from the examination of mining properties near Breckenridge, Colorado.

Obituary

W. C. Greene, who died at Cananea, August 5, of acute pneumonia, the secondary result of being thrown from a carriage by a runaway team, is mainly known for his connection with the Greene-Cananea Copper Co. He was one of the picturesque pioneers of the Southwest who turned promoter and did much to attract attention to the region in which he made his home. Beginning as a Government contractor in Colorado and Kansas, he was successively prospector, miner, and company organizer. He acquired the title of Colonel while leading volunteer forces against the Apaches in the early eighties. He nearly lost it when, after breathing dire threats of extermination, he met a certain other Colonel from Boston. It is said that the conversation between the two Colonels closely followed the lines of the historic *pour parler* between the Governor of North Carolina and the Governor of South Carolina. After the reorganization of the Cananea company, Mr. Greene devoted the major part of his attention to his immense cattle and farming interests in Sonora. He was one of a type that is fast disappearing from the Southwest.

DENMARK will hold an International Marine Motor Exhibition at Copenhagen in July and August next year. Applications for space should be made through any of the Royal Danish Consulates.

AIR-COMPRESSORS are widely used, but there is a surprising lack of exact data regarding them and indeed many features of the use of compressed air. We are glad to present this week the first of a series of short practical articles written by Mr. R. L. Webb and based upon his experience in running tests, particularly an elaborate series but recently concluded at Cobalt, Ontario.

TO THOSE who have time to stop to reflect, amid the hurry of modern life, the changes which the last few decades have wrought in our national life and the national habit of mind are astonishing. A short while since ten thousand citizens gathered to see the first spadeful of earth removed in the construction, by the municipality of New York, of a subway which is to cost three hundred millions of dollars. Probably the larger number of those present were scarcely as much interested as they would have been in the passing of a circus parade, yet the magnitude of the work and the fact of its being undertaken by the municipal authorities strikingly exhibits the sweeping changes which have come as a result of enormous development of city and nation.

MINNESOTA is strengthening its State University, and we are especially pleased that the geological department is among those to receive help. Mr. W. H. Emmons has been called to the chair of geology and will serve as state geologist, the Geological and Natural History Survey of Minnesota being under the direction of the regents of the University. Mr. Emmons will be recalled by our readers as the author of an interesting series of articles on 'Outcrops of Orebodies,' and by engineers generally as having written an illuminating discussion of the rôle of manganese in secondary enrichment of gold ores. He is one of the most brilliant of the younger American workers in economic geology and will undoubtedly serve with distinction in the position to which he has been called.

'STIRRING the passions of the vulgar horde' is an easy way to obtain notoriety, but when coldly considered is usually seen to be an immoral use of the baser elements of human nature. The recent action of Mr. J. K. Vardaman, newly elected United States Senator from Mississippi, in appearing upon the streets of Meridian dressed in white, sitting in a white chariot drawn by 160 white oxen in order to advertise his candidacy by emphasizing the color line between the two races, was a theatrical display which deserves the condemnation of all right-minded men. The race problem is a pressing one in many places, including our Southern States, but no good purpose can be served by such appeals to unreason as have characterized Mr. Vardaman's whole public career. It is a strange commentary on Mississippi that he is to be sent to Washington as the associate of the scholarly and able Mr. John Sharp Williams, who is now serving his first term in the Senate.

CONCRETE is used widely in battery foundations and heavy blocks are now common. At the Headwaters mill, Baguio, Philippine Islands, a block containing 80 cubic yards was used to support ten stamps. This large amount was made necessary by reason of a tube-mill instead of plates being used below the stamps. The excavation being carried down twelve and a half feet to the tube-mill level, concrete was the most available material for building the foundation block.

FOREIGNERS in Mexico are complaining that conditions have changed greatly since the revolution. In many places, particularly in the remoter towns, they have been called on to face much annoyance and occasional real danger. This, while unfortunate, is to be expected. After a successful war any people is likely temporarily to become overly self-satisfied. Germany has never recovered from her easy victory over France, and in that fact lies the chief menace to the peace of Europe today. The Japanese, after defeating Russia, were for a while considered to hold an exaggerated opinion of their own importance, and, after our own little skirmish with Spain it was the universal opinion of others that Americans had a better opinion of their own prowess than was altogether warranted by the facts. These things are generally temporary, and while they endure call for good-humored forbearance among friends. If the Mexican peon in the first flush of victory considers the scheme of things from a wrong angle, it is well to remember that the past has given him little opportunity for forming sound judgments in matters political and economic. Patience and tact are called for to an unusual degree among engineers in Mexico just now. It is hard to suffer injustice, but that is at times the way of life. The best thing any friend of Mexico can do now is to keep as many Mexicans as possible exceedingly busy. Idle hands make repeated revolutions easy.

ONE striking and interesting feature in the foundation of Michigan College of Mines was the fact that the initiative came from a young man, a graduate of a technical school, and that his main concern was the benefiting of the practical men already in the mines. Mr. J. Parke Channing, to whom more than anyone else the school is due, in his letter to the Marquette *Mining Journal*, January 7, 1885, emphasized the need of broadening the outlook of the mining captains and under-bosses. Despite the excellent work done at Houghton and elsewhere since 1885, that need is still acute. There are enough schools for engineers, but even now there are not enough opportunities for the men in the ranks. At Houghton itself emphasis appears now to be placed mainly on training engineers, and this seems to be the universal drift in technical schools; they work away from the men instead of drawing the latter to them. This may be in the line of evolution. We are glad to note, however, the fidelity with which the school at Houghton has followed the main principles laid down at the time of its founding, as Mr. Channing enumerates them on another page. It is instructive to note also the large results that have followed from relatively small effort on the part of one man. Mr. Channing, when he took up the matter of founding the school, was but a recent graduate, a subordinate in a minor State office, and a stranger to most of the people in Michigan. Yet he had the foresight to sense the need and the means of meeting it and the initiative to undertake the matter. This called out coöperation, as it always has and always will, and the greatest benefit has ensued. The whole matter carries a lesson of individual responsibility and of personal opportunity. In the face of the results of Mr. Channing's work no engineer should despair over the possibility of benefiting his profession.

ARIZONA statehood seems likely to be still further deferred since the President has refused to sign the joint resolution admitting Arizona and New Mexico. The merits of the original question, whether judges should be subject to recall, have disappeared in the larger one whether the people of Arizona shall have the form of government they want without resorting to trickery. It is everywhere conceded that once in the Union, Arizona could enact any law on this subject that pleased its people. This, we think, completely nullifies any force which might lie in the President's objections to the new constitution. Whether we like or dislike the notion of recalling judges, to adopt the recall system does not destroy republican government, and so long as that is true it is a matter for decision by the people of Arizona rather than the Nation. We sincerely hope the resolution will be passed over the President's veto.

Taking Things for Granted

There is a well known story of the youthful lawyer who was called upon to argue his first case, an ordinary trespass suit, before an old and learned judge. Fired with the enthusiasm of youth, he began with a sketch of Roman law, followed with a summary of Blackstone, and was about to recite the United States Civil Code, when the judge interposed: "Young man, in the Supreme Court of Massachusetts you may take some things for granted." Everyone has some time felt the embarrassment of being subjected by a chance acquaintance to a long and frequently faulty exposition of some subject with which the listener is perfectly familiar. But, on the other hand, everyone has at times been equally embarrassed by the omission of essential information in a statement, letter, or report. The emphasis therefore shifts to the essential point; the taking of things for granted only when it is safe to do so. It is safe to say that the average business man has in his daily life, more conversations to listen to, more pages to read, more letters to write, and more things to do than he can well afford the time for. The elimination of the unnecessary is a constant problem. The waiter's shout of "ham and" is a frequent source of amusement, yet if he occupied the time and attention of the cook with "please prepare two fried eggs together with fried ham," he would probably, and properly, get his deserts with a dish-mop.

Much of the slang current in America finds its origin in this effort to be concise and definite, substituting for words that have several meanings another applying only to something definite. Such an uncouth word as 'muck' is derived thus. That term is widely used for the material broken down in driving underground; this is usually waste, at times hard rock, at others clay, but it may be ore, and is frequently a mixture. A 'mucker' is the man who loads it into cars and trams it to the loading station. This unattractive slang is almost typical. Muck already had four well known meanings, two of them colloquial, before its use in this connection, so that instead of attaining the aim of brevity and conciseness, increased confusion results from the use of a word which has unpleasant associations. Another characteristic of slang is that it frequently takes so strong a hold upon the fancy of the unthinking public that instead of being restricted to a definite usage it is applied in the loosest possible fashion and degenerates into the patois of the uneducated, and, having thus burst the bubble of its temporary utility, soon drops from sight. A small percentage of words survive and, fighting their way into good society, finally attain a place in the Who's Who of philology without even the tell-tale [colloq] to mark their humble origin. Abbreviations are a legitimate and common method of securing conciseness, and stenography and the typewriter are among the many aids to brevity and speech that [illegible] be devised. There always springs up in each circle of men of similar interests a special vocabulary, so that a lawyer would be at a loss to understand a conversation between two physicians, while both would be puzzled by the phraseology of a stockbroker. But an intelligent physician would not use the same phrases to a layman as to another physician, nor should engineers attempt in writing to use the colloquialisms of the mine and mill.

A Public-Lands Convention

Denver is to entertain a public-lands convention September 28, 29, and 30, this year, the call having been issued by the Governor pursuant to a joint resolution by the legislature. Only those States containing 1,000,000 or more acres of public land are invited to send delegates. The purpose of the convention is stated as follows:

"The real issue is whether the public domain, other than the little remaining farming lands, shall be held in perpetuity by the National Government free from taxation by the States, to be administered by leasehold for revenue for the Federal treasury, and under bureaus at Washington."

The problem of the public lands is one of the most important before the people today, and in it those of the Western States has a peculiar interest. At the same time it is a National problem, and, rightly or wrongly, it will be settled by representatives of all the people. Assuming that there is a distinctly Western viewpoint, and that it differs markedly from that of the East, the practical problem is whether we are most apt to reach a fair consensus of opinion by Western men holding a separate convention, or by inviting as many Easterners as are willing to come and see conditions as they actually exist. As a general rule, there can be no question that unity is promoted by getting together and threshing things out. Also, it is easier to convince your opponent when you have him in your territory and surrounded by your friends than when you invade his domain, backed by resolutions never so resounding. As a matter of fact, we doubt whether the call reflects fairly the viewpoint of the West, though it does undoubtedly voice the sentiments of a large element, possibly the majority. Once before, a public-lands convention met at Denver, but, greatly to the surprise of its proponents, it endorsed fully the Roosevelt policies. The ex-President is exceedingly popular in the West, and while there is still much complaint, National Forests and land withdrawals are much less unpopular than two years ago. In practice it is found that better roads and trails are built by the Forest Service without a local levy of taxes than most communities enjoy as a result of taxation, and more than one mining district has been revived as a result of a road built by the Forest Service, as readers of our news columns will have noted. The allotment of revenue from the forests to the local counties does much, too, to destroy the point of criticism relative to removing vast areas from local taxation. The forests, our only example of National administration, are not run 'for revenue for the Federal treasury', and anyone who will re-read Mr. Roosevelt's proposals regarding leasing coal lands must recognize that he at least never proposed that plan as a means of raising revenue. Indeed, we are not aware that any Federal officer has proposed a royalty on coal higher than that exacted by Colorado from State leases. The leasing system has been proposed, not as a revenue measure, but to prevent monopoly and secure better and more systematic development. It is capable of plain demonstration that these results have followed in other countries where the system has been adopted; and that, too, where the conditions and the people are not dissimilar to those of our Western States. There is room for much difference of opinion regarding the utilization of the public lands, and need for much discussion to effect an enlightened public opinion, but we are doubtful as to the finality of any conclusions likely to be reached by the Denver convention.

Investment and Speculation in Mining

Yukon dispatches announced lately that Mr. A. N. C. Treadgold had secured the cooperation of Mr. John Hays Hammond and the Consolidated Gold Fields of South Africa, in the formation of a new corporation rivaling Yukon Gold in importance. This is now denied by Mr. Hammond, so far as concerns his own participation in the negotiations and the enterprise, though he states that the Gold Fields company has taken a small interest in the new Yukon enterprise. Mr. Treadgold has been known to have been quietly buying ground at Dawson, and, whether now or later, will undoubtedly form a corporation for work on a large scale. Among properties mentioned as going into the new corporation are the Boyle concession and the Northern Light, Power & Coal Company. There is abundant room for a second big company at Dawson, and ground from which profit can be won only by large-scale dredging. The new enterprise will have the good wishes of mining men. Denial of the report that the Consolidated Gold Fields of South Africa is largely interested in the Yukon calls attention to the fact that so far that active group of investors has been unable to do much business in America. Both the deals for the Golden Cycle at Cripple Creek and the Rea Consolidated at Porcupine, as well as reported heavy purchases at Guanajuato, fell through after they had been announced as completed. We are not informed as to the details in any of these cases, but the truth seems to be that buying mines is conducted differently in England and America. Investment is emphasized there and speculation here. It is all too common in the United States to consider mining as entirely speculative, anyway, and therefore to capitalize from the first the maximum possible profits. It is very generally true that shares in an American mining company sell for higher prices than is shown to be warranted on any careful analysis of data supplied by the company itself. As a broad general statement, purchase of shares in America, and particularly of mining shares, is determined more by who are in the company than by what is known to be in the mine. We do not deprecate speculation. Buying shares with a view to selling them later at a higher price is a common and innocent form of making money—and also of losing it. It is not, however, for the best interest of mining and of mining men, at least as we see it, that attention be centred too exclusively upon that phase of the business. Mines may be and should be run so that strictly on the investment basis purchase of shares is as well warranted as is the purchase of shares in industrial enterprises. For the younger men of the profession particularly, it is important that attention be centred first on this phase of the business of mining. Many a promising career has been ruined by too early participation in speculation in mining shares. One of the most successful, financially, among American mining engineers confined his activities absolutely to operation and examination for over twenty years after leaving the mining school. Then, with seasoned judgment and a masterly grasp on the technical operations of mining, he participated in financing and promoting properties, with eminent success. His own point of view is somewhat fatalistic, since he holds that if an engineer has 'financial sense' the opportunity to use it will come to him by the time he is ready. This whole subject has been discussed here before, and has recently been well put in *The Mining Magazine*, but its importance warrants repetition.

Buying Air-Compressors

By R. L. Webb

In mines and quarries the air-compressor is often the most important part of the mechanical equipment, as upon it depends the operation of the drills, and, in many cases, the pumps and hoists. Any accident to the compressor would mean an expensive shut-down and possible flooding of the mine. This being true, all that is usually considered when purchasing a compressor is continuity of service, cost, and delivery. In few instances are any guarantees asked of efficiency, output, and steam-consumption. When questions of efficiency are raised, the answers given are misleading in that they are often only in part correct. This is possibly because of the dearth of reliable data. It often happens that selection of a compressor of high efficiency, well adapted to the work, and of low steam-consumption, though at a somewhat higher cost, will save enough in the cost of fuel annually to amount to a high dividend on this additional investment.

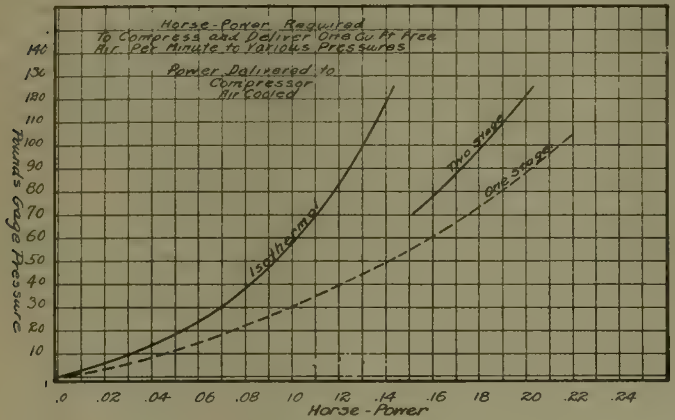

Fig. 1.

Air-compressors are usually rated by their displacement, which is the volume of the cylinder in cubic feet times the revolutions per minute. Generally no deduction is made for the rod. In multi-stage compressors the volume of the low-pressure air-cylinder alone is considered. The air-compressor is a machine for changing one kind of energy to another, taking in mechanical energy from a steam engine, electric motor, or other source, and delivering compressed air. In principle it is somewhat similar to an electric generator, which, driven mechanically, delivers power in the form of electricity. As such apparatus absorbs in friction and other internal losses some of the energy delivered to it, the true efficiency is the foot-pounds delivered as a percentage of that put into the machine; in other words, output divided by input. The difference between these is the loss in conversion, which includes all the losses, and not any one particular loss which is only a part. Many salesmen when asked for the efficiency of their compressor, will quote a figure that is the indicated horse-power of the air-cylinder stated as a percentage of the power delivered to the machine. This is misleading, since it only allows for friction and takes no account of the other inherent losses of compression. Another answer sometimes given is that the output is a certain per cent of the displacement. This, too, is only partly correct, and therefore misleading. The air-compressor has been given so many horse-power applied in the steam-cylinder, or on the pulley, as the case may be, and the per cent of this that is actually delivered in compressed air available, is the true efficiency. Manufacturers of electrical apparatus will unhesitatingly guarantee the efficiency of their apparatus, and they educate purchasers as to what is meant by it. Strange as it may seem, the question of true efficiency (output over input) is avoided by many compressor manufacturers and the purchaser does not have it explained as it should be.

To determine the energy delivered from a compressor, multiply the cubic feet per minute output by the horse-power required to isothermally compress one cubic foot of free air to the desired pressure in one minute. Figures of isothermal compression or compression without any increase in temperature, should be used because, although the air leaves the compressor hot, it loses this heat rapidly, and this should be considered as a part of the loss. Fig. 1 shows the horse-power required in the air-cylinder to compress one cubic foot of free air per minute to various pressures isothermally, in one and two-stage compression. These curves are taken from the standard authorities, and many points have been checked from actual tests. The one and two-stage curves are based on adiabatic compression plus 15 per cent.

To get the output of a compressor by actual test, the easiest method is by the use of standard orifices, using Fleigner's equation for the flow of air through an orifice; but when this cannot be done, a fairly good method is to consider that the machine compresses the air adiabatically and divide the indicated horse-power of the air-cylinder by that shown on Fig. 1 for one or two-stage compression, as the case may be. This will give a close approximation to the real output.

When purchasing an air-compressor, the first point to be considered is the capacity needed. This can be determined from Fig. 2, which takes into account only the actual working time of drills. If pumping is done by compressed air and the compressor has to be operated under light loads, Sundays, nights, and holidays, it will be well to consider an additional unit to take care of this light load, since the cost of operating any compressor increases rapidly as the demand for air decreases. This is a matter which should be considered separately for each plant in order to decide whether the saving in operating cost will pay for the additional investment. Aside, however, from the actual saving in operating cost, this arrangement gives a better chance to keep the main units in repair.

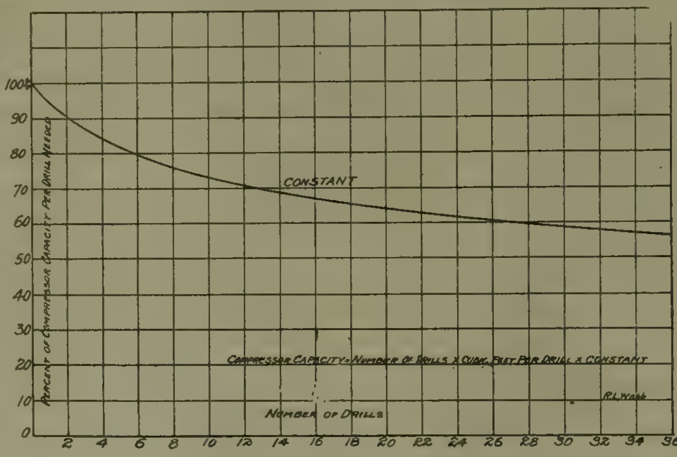

Fig. 2.

The question of whether to use one-stage or two-stage compressors depends on the pressure which will be needed, and is a matter of simple calculation which can be made from Fig. 2, but to obtain the full saving, it is absolutely necessary that the intercooler between the stages be of sufficient size so that the partly compressed air enters the high-pressure cylinder at its initial temperature. Multi-stage compression is frequently condemned because of this, as the compressor manufacturers are driven, by too close buying and unscrupulous competition, to cut down the cooling surface in the intercooler. In all cases the manufacturer should guarantee that with circulating water of a stated temperature the air will leave the intercooler at the initial temperature. It should also be required that the intercooler have hand-holes so placed and large enough to permit it to be kept clean. The cylinder walls and heads should be well jacketed and have good circulation, and with no dead spaces, so that these surfaces may be kept cool. It is true that jacketing does not cool the air during compression to any great extent, but it does have a great effect on the output of the compressor. *For each 5° F. increase in temperature, the volume of air increases 1%.* Thus, if the air entering the cylinder on the suction stroke meets hot surfaces, it at once increases in volume and the density is less than that of the atmosphere. This, when it occurs to any great extent, can be seen on indicator cards.

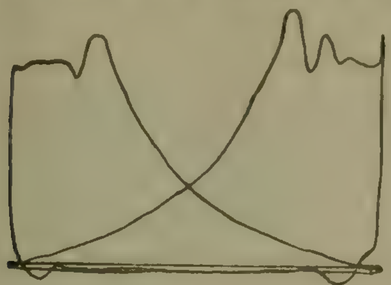

FIG. 3A.

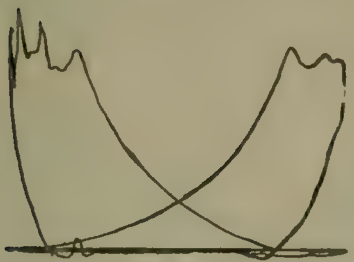

FIG. 3B.

The type of suction valves to be used is debatable, but it is important that if poppet valves are used they be so placed that the air drawn into the cylinder is as cold as possible. In all cases, it should be drawn through a duct from the outside and *not from the hot engine-room.* I have seen as high as 10% loss from this alone. When mechanically operated suction-valves are used, it is easy to connect the suction inlet with the outside air. The area of the suction valves should be ample, so the density of the air in the cylinder at the beginning of the compression stroke will not be less than that of the atmosphere. In most compressors the discharge valves are of the poppet type. They should be of sufficient area. In both suction and discharge valves the speed at which the compressor is operated affects the areas so that no rule can be given. It is extremely important that all valves should not be too tight or too loose and adjustable.

Every compressor should have all the cylinders tapped for an indicator, so that cards may be taken at regular intervals. These will indicate unsuspected troubles that cause waste of power. The clearance should be as small as is compatible with safety in operation. The clearance, or space between the piston when at the end of the compression stroke and the discharge valves, is at this period filled with compressed air which, as the piston moves back on its suction stroke, must expand until it is at or slightly below atmospheric pressure before a new supply of free air will enter the cylinder. The effect of this is to cut down the output, and in the card shown in Fig. 3A, the loss from this and possibly a discharge-valve leak, which latter could not be detected, was 20 per cent.

In most compressor plants the load or demand for air varies greatly. In direct-connected steam-driven compressors the pressure is kept constant or nearly so by an automatic throttling governor connected to the air discharge and controlling the speed by opening or closing the steam valve. This is called throttling. The Meyer valve, which is a slide-valve with an adjustable cut-off, is commonly used. The point of cut-off can be changed by hand and is not automatically regulated. This valve has been successfully applied quite generally where the speed varies and the compressor operates at low speeds most of the time with an occasional demand for full speed; for example, where there is an average of 35% of normal and operating mostly under 50%. For this condition, which is the one usually existing in the class of plants under consideration, I would give this valve the preference over the Corliss, but where the speed is over 50% the greater part of the time, the Corliss is more economical. The Corliss valve is intended to maintain a constant speed with varying load by automatically increasing or decreasing the point of cut-off. In the steam-driven air-compressor with its throttling governor in conjunction with Corliss valve gear, it was found that at below 50% of rated speed the Corliss release did not operate because of the throttling effect and that nothing was gained despite the increased cost of this gear.

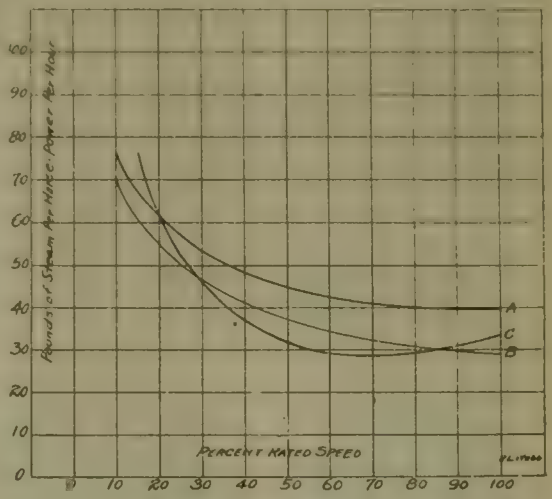

FIG. 4.

All of these types of gear may be compounded and also operated condensing, but the saving obtained by these refinements has to be considered in each case to determine whether it will pay for the increased investment. This is largely a matter of the cost of fuel and the class of labor available.

In all steam-engines the steam-consumption per horse-power increases with any decrease of load or speed. This applies to steam-driven air-compressors. This is shown on Fig. 4, which gives the steam-consumption per horse-power per hour as affected by speed of several types used.

With compressors operated by an electric motor, the varying demand for air is controlled by a weighted valve so arranged that when the pressure rises, the air churns from one end of the cylinder to the other, thus cutting down the consumption of electric current. This valve generally works on an exceedingly small difference in pressure; as low as a pound. The saving obtained by this method of regulation is much less than generally supposed, as there is considerable power used in churning the air, as well as in overcoming the friction of the compressor, so that in a number of cases tested it was found that it required from one-third to one-half as much power to operate the compressor with the unloader in use as when compressing against full pressure. The exact amount can easily be determined by a wattmeter and by timing the respective periods when the compressor is working and 'running light'. Under these conditions the use of an automatic pressure regulator to control the motor, such as is seen on the electric street-cars when air-brakes are used, is to be recommended. This device will automatically stop the motor and the use of electric current when the pressure reaches an adjustable predetermined point, and will also automatically start the motor when the pressure falls to another adjustable predetermined point. The starting and stopping points are separately adjustable. In most cases a ten-pound range can be allowed without any noticeable effect in the working of the machines, five pounds above normal as the stopping point, and five pounds below as the starting point. It can also be so equipped that an electrically controlled unloader will enable the compressor to start up light and not start compressing until full speed is attained. This latter device does away with an excessive starting load. By the use of this device I, in one case, saved a client 30% of his power bill without any noticeable effect in the operation. There are two of these devices on the market which have given satisfaction.

There is also a new type of control where the compressor is run at constant speed and the varying demand for air is taken care of by controlling the amount of air admitted. This is a step in advance, and is well worth considering in the larger-size units.

Grinding Wheels

At the third annual convention of the American Railway Tool Foremen's Association, at Chicago recently, H. E. Blackburn, of the Erie railroad, made the following pertinent suggestions, as reported in the *Railway Age Gazette*.

If Webster were to come back and make a trip through a modern shop, he would certainly have to revise a few things about "to grind." Instead of a slow, severe, continuous process of rubbing of material, his definition would read: "a rapid cutting process of reducing material to accurate size." The old method of reducing metal by machining it in the lathe and leaving it large enough to allow for filing and polishing to size, never did permit round or straight work. The next move was to machine the metal and allow enough to finish on the universal grinder. Now cast metal or drop forgings are made large enough to grind to size from the rough in some form of an automatic grinder, thus eliminating all machine work and allowing hardened surfaces to be finished to accurate sizes.

Just as much judgment is required in selecting wheels and speeds, as in selecting tools, speeds, and feeds for machine work. While no absolute rule holds good in ordering wheels, when you ask for soft wheels, most of your troubles are over (that is, if you can get them). The storekeeper may tell you that he notices that hard wheels last longer. Well, so does the work you are trying to get out. The management may say that the soft wheels wear away too fast, and that they do not keep their shape. Cobblestones, flour, or emery and glue, do not go far in making up a wheel in this progressive period. Still there are a few firms trying to convince you that it is a good combination. With such grits as alundum or carborundum you can pass over the question of material used, and study the grain and grade. If the grains, commonly called grit, are too fine, they soon clog up. If the grade is too hard, the grains, fine or coarse, cannot break away to expose a new set, and the work becomes burnt. There is only one place that you can use a hard wheel—put it on a bolt for a washer.

If you are allowed soft wheels of from 40 to 60 grains, you can grind or finish all the work that comes to a tool-room. Do not be deceived into believing that it takes a 90-grain wheel to do finished work. A good all-around grinding and finishing wheel is a 24 to 36-grain mixed soft wheel, speeded up to a mile per minute surface speed if it is allowed plenty of water; with a traverse feed of ¾ the face of the wheel to one turn of the work, you will have a fine finish. If you wish to take a roughing cut, use from 15 to 30 ft. per minute feed.

Keep the face of the wheel as narrow as possible. Wide faces on small work cause chattering, a fatal thing for both work and wheels; a ¼-in. face on 8-in. wheels is a good size, but if you value your good looks, use the elastic wheel instead of the vitrified when using these slim widths in deep gashes. A wheel that works well on large work does not, as a rule, cut well on small work, and it is always advisable to use the smallest wheel that the work will admit of, so as to get a good clearance. Cast iron or steel requires a soft coarse wheel. Rolled iron or steel requires a soft medium wheel. Cast or rolled brass requires a soft fine wheel. A good rule is, the harder the stock to be ground the coarser the grain of the wheel, and all wheels should be soft enough to be scratched with a scriber before you mount them for use.

While it is necessary now and then to violate tradition in order to do the work with what wheels you may have left over from your first order, avoid the slim, slick-looking hard one, for, like the aeroplane, it will do stunts in the air; and remember that the devil himself cannot make one wheel for 'all comers', if he can furnish the sparks. Teach the operator to have the wheel fit the arbor 'neat'. Be sure the arbor and washers run true, and that the drive-washer is keyed on the arbor, this washer to be one-third the diameter of the wheel. Use rubber pads between the washers and the wheel; don't allow the operator to jam the nut with a hammer. When everything runs dead true, you can feel safe for a good job, as a wheel out of true is only a one-eighth producer.

True the wheel with a diamond, and dress it frequently with a spur cutter. Instill into the operator's mind that dressing is not trueing. With rough diamonds at $12 mounted, there is no excuse for not having one. The operator should dress and true the wheel between heavy and finishing cuts.

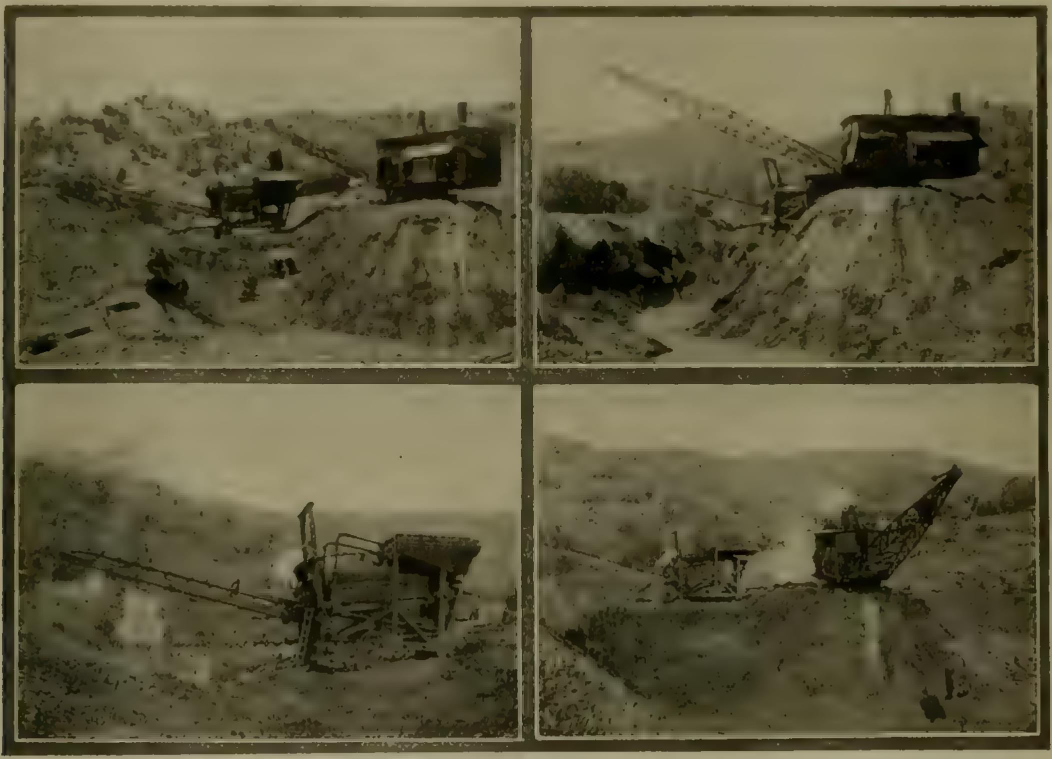
Remember that old machines and methods and slow operators soon start a graveyard in any shop. Keep clean and set the example for the operator to do likewise. If you wish to find out all the bad points about the wheels you are using, ask the wheel agent of a rival firm—you will be surprised at the outburst. Last of all, do not condemn any wheel until you have tried it on different metals with variable speeds and feeds.

SMALL HAMMER DRILLS are used with a chisel bit in the Hecla mine at Burke, Idaho, for cutting off the crushed ends of timbers. In the stopes the greatest pressure is from the squeeze of the walls, and as the ends of the stulls and caps become splintered and crushed, it is necessary to cut them off and put in new blocking. It is often difficult to get at the crushed timbers, and, even when accessible, it is not an easy job to chisel or saw the wet and twisted fibers by hand. The cutting of the wood is rendered quite easy with the drills, and by using sufficiently long bits, almost any desired place can be reached. The drills and chisels may also be used to great advantage for chiseling wall plates when an extra shaft compartment must be added, or in cutting off posts to ease up drift sets in heavy ground. In a number of mines, the blocking on drift caps is shot out when it is necessary to ease up on the sets; this work can much more safely and surely be accomplished with the drill.—*Ideal Power*.

SURPLUS COPPER STOCKS are lower now than at any time since February 1909, two and a half years ago. This fact can have but little effect in the present condition of business, but would form an excellent basis on which to work in the case of a business revival.

Bucket Scrapers in Dredging

Inquiries have been made for further particulars regarding the bucket scraper used by the Calaveras Engineering Co. in gold dredging and described in our issue of June 17. We therefore present below views showing details of both the bucket scraper and the washing apparatus. The scraper was originally developed for use in ordinary excavation. C. W. Purington, in 1909, saw the machine in operation in levee building at Muscatine, Iowa, and, recognizing the possibilities of the apparatus, purchased one for use at the Kolchan mines in Siberia. Views of this scraper in use handling accumulated tailing were published in the *Mining and Scientific Press* July 9, 1910, and in our issue of February 11, 1911, Mr. Purington presented full details of its operation. In Siberia the scraper was used to dig tailing from old placer workings, delivering to a sluice. It was erected in three weeks after arrival and made a cut 120 ft. wide and 27 to 30 ft. deep. Owing to insufficient water-supply, the machine was not operated continuously, but during the 59 days that it was in operation, 593 cu. yd. per day was handled; equivalent to full capacity $16\frac{2}{3}$ days of 24 hours each. Mr. Purington estimated that with sufficient water for steady sluicing, a capacity of 1750 yd. could be maintained with 20 hr. work per day. This year the scraper is delivering to a series of gold-saving tables similar to those on a dredge. These have been mounted on a scow floated in a pond following the scraper, which is now working in undisturbed gravel. The San Andreas bucket scraper illustrated in the accompanying figure, delivers to a set of similar trommels and riffles, in this case mounted on rails. The excavator rests upon rollers by which it is moved on a plank track. It has a 60-ft. boom upon which the scraper-bucket works, weighing $1\frac{1}{2}$ tons, and having the capacity of $1\frac{1}{2}$ cu. yd. The bucket is raised and lowered by means of a hoisting cable working over a sheave at the end of the boom; it is loaded by means of a drag-line running between a set of traveling sheaves in front of the floor plate. The loading and dumping is accomplished by means of an equalizer cable attached to the drag-line and front of bucket, and which passes over a sheave fastened to the bucket bail. The excavator has a bottom plate of steel, 14 ft. square, a 14 by 28 ft. floor plate of steel; between the two plates is a turn-table of 12 cast wheels resting on 80-lb. rails. The machine is turned by a single drum winding engine, having two cables attached, whereby a complete circle can be made and the buckets operated on all sides. The machine is operated by steam power, wood being used as fuel. Thus equipped, it has excavated to a depth of 45 ft., and can be worked to a depth of 50. The channel being dredged contains a considerable amount of barren clay, occurring in layers. By utilizing the equalizer cable on the bucket the operator is able to excavate in layers, and thus remove the clay. It requires two men on the excavator, one to operate, the other attending to firing, water supply, and oiling; one man is required on the washer. All bedrock material, except the limestone, can be excavated by the bucket.



BUCKET SCRAPER AND GOLD-SAVING PLANT, SAN ANDREAS, CALIFORNIA.

The material is dumped by the bucket into a 12 by 12-ft. hopper, from which it passes into an iron cylinder, $4\frac{1}{2}$ by 22 ft., which revolves at 12 to 15 r.p.m. The upper part of the cylinder has $\frac{3}{8}$-in. perforations, those in the lower 18 in. being $\frac{3}{4}$ in. The oversize discharges upon the stacker, by which it is carried to the dump; the undersize passes into an iron box lined with Hungarian riffles, in which 80% of the saving is made. The sand and gravel are then carried to a riffled sluice-box in which quicksilver is deposited, and finally to a 20-ft. sluiceway in which cocoa matting is used for recovering the fine gold. The cylinder and stacker are operated by a 15-hp. electric motor.

A somewhat similar bucket known often as an 'Oregon scraper' is frequently used in the West for shallow digging. It is handled by means of lines from a donkey engine and the bucket is so shaped that a pull on the main line forces it to dig into the ground till full. Such a bucket gave good service at Treadwell, Alaska, this summer while excavating in hard boulder clay, for storage-bin foundations. This device has been applied to placer mining near Oroville and was described by H. W. Turner in the *Mining and Scientific Press*, August 8, 1908.

Government Specifications for the Purchase of Fuel Oil

By Irving C. Allen

*Until within a few years fuels were generally bought solely on the statement of the seller. The consumer made little effort to find whether value was received for the price paid, but relied on the integrity of the dealer and the brand or trade name of the fuel. Recently, however, the plan of purchasing coal according to specifications of quality, especially heating value, has gained favor. In consequence of the success that has attended the use of heating-value specifications in buying and selling coal, there has arisen a demand for similar specifications, based on careful tests, to govern the purchase of fuel oils and the refined products of petroleum. These specifications, to be satisfactory, should establish not only the heating value of the oil, and thus show, like the specifications for coal, the number of heat units the purchaser obtains for a given price per unit quantity of fuel, but also the physical character of the oil, its flash point and burning point, and the quantity of extraneous matter it contains.

The Bureau of Mines has received many inquiries from Government bureaus and from private concerns regarding fuel-oil specifications and the sampling of purchases. In reply to these inquiries the bureau has issued a report, which, although intended primarily for the guidance of Government officials, may be of service to all persons who buy or sell fuel oil.

(1) In determining the award of a contract, consideration will be given to the quality of the fuel offered by the bidders, as well as the price, and should it appear to be to the best interest of the Government to award a contract at a higher price than that named in the lowest bid or bids received, the contract will be so awarded.

(2) Fuel oil should be either a natural homogeneous oil or a homogeneous residue from a natural oil; if the latter, all constituents having a low flash point should have been removed by distillation; it should not be composed of a light oil and a heavy residue mixed in such proportions as to give the density desired.

(3) It should not have been distilled at a temperature high enough to burn it, nor at a temperature so high that flecks of carbonaceous matter began to separate.

(4) It should not flash below 60° C. (140° F.) in a closed Abel-Pensky or Pensky-Martens tester.

(5) Its specific gravity should range from 0.85 to 0.96 at 15° C. (59° F.); the oil should be rejected if its specific gravity is above 0.97 at that temperature.

(6) It should be mobile, free from solid or semisolid bodies, and should flow readily, at ordinary atmospheric temperatures and under a head of 1 ft. of oil, through a 4-in. pipe 10 ft. in length.

(7) It should not congeal nor become too sluggish to flow at 0° C. (32° F.).

(8) It should have a calorific value of not less than 10,000 calories per gram (18,000 British thermal units per pound); 10,250 calories to be standard. A bonus is to be paid or a penalty deducted according to the method stated under section 21, as the fuel oil delivered is above or below this standard.

(9) It should be rejected if it contains more than 2% water.

(10) It should be rejected if it contains more than 1% sulphur.

(11) It should not contain more than a trace of sand, clay, or dirt.

(12) Each bidder must submit an accurate statement regarding the fuel oil he proposes to furnish. This statement should show: (*a*) the commercial name of the oil; (*b*) the name or designation of the field from which the oil is obtained; (*c*) whether the oil is a crude oil, a refinery residue, or a distillate; (*d*) the name and location of the refinery, if the oil has been refined at all.

(13) The fuel oil is to be delivered f. o. b. cars or vessel, according to the manner of shipment, at such places, at such times, and in such quantities as may be required.

(14) Should the contractor, for any reason, fail to comply with a written order to make delivery, the Government is to be at liberty to buy oil in the open market and charge against the contractor any excess of price, above the contract price, of the fuel oil so purchased.

(15) Deliveries of fuel oil will be sampled by a representative of the Government. Whenever such action is practicable, the oil will be sampled as it is being delivered. The final sample will be made from samples taken from as large a proportion of the delivery as practicable, in order that the final sample may truly represent the delivery.

(16) The final sample will be sealed and forwarded to the Federal Bureau of Mines, Pittsburg, Pa., for analysis.

(17) If the contractor so desires, permission will be given him, or his representative, to witness the sampling of the delivery and the preparation of the final sample.

(18) The final sample will be analyzed and tested immediately after its receipt at Pittsburg.

(19) A contract entered into under the terms of these specifications shall not be binding if, as the result of a practical service test of reasonable duration, the fuel oil fails to give satisfactory results.

(20) It is understood that the fuel oil delivered during the term of the contract shall be of the quality specified. The frequent or continued failure of the contractor to deliver oil of the specified quality will be considered sufficient cause for the cancellation of the contract.

(21) Payment for deliveries will be made on the basis of the price named in the proposal for the fuel oil corrected for variations in heating value, as shown by analysis, above or below the standard fixed by the contractor. This correction is a pro rata one and the price is to be determined by the following formula:

$$\frac{\text{Delivered calories per gram (or B. t. u. per lb.)} \cdot \text{contract price}}{\text{Standard calories per gram (or B. t. u. per lb.)}} = \text{price to be paid.}$$

Water that accumulates in the receiving tank will be drawn off and measured periodically. Proper deduction will be made by subtracting the weight of the water from the weight of the oil deliveries.

These specifications provide for the purchase of fuel oil by weight. As such oil is frequently delivered by volume, it is important to note the temperature of a delivery and to allow for the expansion due to this temperature when computing the weight of the delivery from volume. From the volume of the oil at the temperature of delivery, the volume at standard temperature (15° C.) should be computed in the manner given below.

The coefficient of expansion of ordinary fuel oil residues of asphaltic base is approximately 0.0006 per 1° Centigrade.

Hence if the temperature (N° C.) of the delivery is above 15° C., then (N° C. – 15° C.) × 0.0006 = correction. This correction is to be added to the specific gravity at N° C. to give the standard specific gravity, that at 15° Centigrade.

If the temperature (N° C.) of the oil delivered is below 15° C., the correction ([15° C. – N° C.] × 0.0006) is to be subtracted from the specific gravity at 15° Centigrade.

Since a gallon of water at a temperature of 15° C. weighs 8.3316 pounds, the weight in pounds of a gallon of oil at 15° C. is 8.3316 times the specific gravity of the oil at that temperature.

Similarly, since a cubic foot of water at 15° C. weighs 62.3425 pounds, the weight in pounds of a cubic foot of oil at 15° C. is 62.3425 times its specific gravity at that temperature.

---

Founding of the Michigan College of Mines

By J. Parke Channing

*In the autumn of 1884 I was asked by A. P. Swineford, ex-governor of Alaska, who was at that time Commissioner of Mineral Statistics for the State of Michigan, to examine and report upon the various copper mines of the State for the forthcoming annual report. Having graduated from the Columbia School of Mines only a little over a year before, and realizing as I do now that the possession of a diploma did not [illegible] knowledge of the mining [illegible], it was with considerable [illegible] that I entered upon this [illegible]. But a few days' work, however, convinced me that everyone was ready to help me, the particularly gracious people being the Cornish mine superintendents and captains, who made allowance for my inexperience, and with their vast fund of practical knowledge guided my steps aright. To such men as James **Dunstan, William Tonkin, Samuel B. Harris, John Daniell,** and Johnson Vivian I was particularly indebted. In talking with them and their various subordinates the question of technical education was frequently discussed, and its desirability for the rising generation was freely admitted. In particular there was a crying demand from the ambitious young and middle-aged men for some means of studying the science of mining outside of working hours.

Early imbued by my mother with the truth of the words of St. Simon that "All should labor for the development, material, moral, and intellectual of the class most numerous and the poorest," and knowing that talent and genius from all conditions rise, I was filled with the desire to found a school, which has now developed into the Michigan College of Mines. I had but lately come from Drifton, Pennsylvania, where Eckley B. Coxe had established a day and night school for the miners, and this seemed to appeal particularly to the men who were working in the mines and who wished to raise themselves from the positions of merely running a drill, to the large and more important places which were ever demanding their services. After finishing my examination and writing my report for Mr. Swineford, in January 1885, I wrote a letter to the Marquette *Mining Journal* stating thoroughly my views on this matter, and suggesting that something be done by the State toward the establishment of a mining school. As has always been the case in respect to meritorious suggestions, the Marquette *Mining Journal* published this letter in full, with favorable editorial comment, and a copy of this issue of the *Journal* found its way to J. A. Hubbell, who as Senator was then representing the Upper Peninsula at Lansing. The suggestion appealed to him, and I remember his writing me asking me to get him some extra copies of that particular issue of the *Mining Journal*, which I did, and sent them on to him. He soon after secured the passage of an act by the Legislature which was approved May 1, 1885, establishing the Michigan College of Mines, which, however, at that time was called the School of Mines, and with it an appropriation of $15,000, in support of the school.

From that time forth Mr. Hubbell devoted his best energies to the development and prosperity of the school, and its success has been principally due to his zealous efforts. I remember soon after the school was started, he told me that had I been older and more experienced, it would have greatly pleased him to put me in charge of the school. While recognizing the justice of his judgment, I could not but admire the wisdom of his choice of Albert Williams, Jr., a graduate of Princeton, to launch the adventure. Mr. Williams remained in charge for two years and then resigned. M. E. Wadsworth, a graduate of Bowdoin and of Harvard, was chosen president next and remained so for a number of years until he was succeeded by F. W. McNair. In the beginning there were no buildings for the School of Mines such as you now see, and the basement of the fire engine building at Houghton was used for class rooms. In September, 188[illegible], some rooms in the Odd Fellows' building were secured, but the continued growth of the school in the summer of 1888 obliged them to take rooms in the Roller Rink building, which afterward became the Armory Opera House. It was not until 1889 that the first building, known as Science Hall, was occupied. This building was erected upon land donated by Mr Hubbell, and this was the forerunner of the present college buildings. In 1890 the Ore Testing Works were constructed, and in 1892 a small building was erected containing some metallurgical furnaces. In 1895 the State erected another large building, which took in the department of Electrical Engineering, Mechanical Engineering, and Drawing, and the office and lecture rooms of the Civil and Mining Engineering courses. From that time on the growth of the school has been steady and its graduates have commanded ever increasing respect for their integrity and capacity in the mining world. From the first sum of $15,000 the annual appropriations have increased, so that the total for the quarter century is $1,182,420. The total number of students registered has been 1563, and the number of graduates 640.

The principles formulated at the time the school became thoroughly organized and its functions defined are given below, and it is hardly necessary to say that they have always been closely adhered to:

1. To keep the school a special one for giving instruction in all branches relating to the development of the mineral wealth of the State and Nation.
2. To give the very best, most practical, and highest education in this field that it was possible to reach with the means at command.
3. That the instruction should always be by laboratory and field methods, or a true union of theoretical and practical instruction.
4. That the school should in its earlier days, put every dollar obtainable into equipment and collections for teaching purposes, and spend nothing for show, until the departments themselves were in a condition to do their proper and designated work.
5. That special opportunities should be given to men of mature or advanced age who had been engaged in practical work, and who wished to obtain an education to aid them in their subsequent labors.
6. That the catalogues and other publications should state, so far as could be known in advance, the exact truth about the school and its instruction.
7. That no one should be appointed an officer in the schools, or be retained therein, for any other reason than his fitness for the place and his capabilities for doing his work.
8. That students in the school must work or leave; and that no distinction should be made among them on account of their wealth, social position, or birth place, the only criterion being their ability to perform their duties. Also that quality and thoroughness of work should be the aim, and not mere numbers of students.
9. That the institution should be managed on business principles, and the professors be allowed to conduct their departments according to their own individualities. They should be held responsible for producing the required results, but not for their methods of bringing about these results. They should have entire choice of, and control over, their subordinates, who were to be solely responsible to them. Further, that the professors should receive from the president every aid and assistance possible in developing their departments, and they should be supported in enforcing proper discipline.
10. That the school should be conducted for the benefit of the students and of the State and Nation, and not for the particular advantage of the town in which it happened to be located, or any special clique. This should be done

---

*Address delivered at Houghton, Michigan, August 8, in celebration of the twenty-fifth anniversary of the founding of the college.

in the belief that in serving the State best the local town would in the end be more benefited than by any other policy.

The Board has always been composed of mining men, and it is greatly to their credit that they have always found time, without prejudice to their especial work, to give the school a full share of their attention.

Although a graduate of the Columbia School of Mines and thoroughly loyal to my *alma mater*, I am convinced that a mining school properly financed and officered, and situated in a mining district like Lake Superior, can not be excelled in the superiority of the instruction it can offer its pupils. I say properly financed, because when so conditioned it can in a great measure offset the advantage usually enjoyed by larger schools in large cities, of being able to offer temptingly large salaries, and thereby draw from smaller schools men who have demonstrated their efficiency as instructors. Hence the word 'success' when associated with a school, inadequately financed, is often but a prediction of its sooner or later failure, by reason of its inability to long retain a sufficiently large corps of able teachers. The State of Michigan derives much revenue from the mines, both directly and indirectly, and it should not be niggardly in its appropriations for the Michigan College of Mines. When men realize that the more numerous the prosperous and educated in the community the greater the guarantee of individual happiness and prosperity, then they will cheerfully endure any amount of taxation. The State must in self-defense educate the masses.

Germany recognized the necessity and advantage of having a mining school in a mining district, when it established a School of Mines at Freiberg and one at Clausthal. It is difficult to describe a mine to a student, and while a great deal of preliminary instruction is purely scientific, yet it is better that a student see a mine than attempt to evolve it out of his inner consciousness, as the German philosopher did the elephant. Schopenhauer in his 'Essay on Education' lays stress on the fact, that "the main endeavor in education must always be to let particular observations precede general ideas and not vice versa, as is usually and unfortunately the case." It has been truly said that objects may be segregated and studied through a tube; but their combinations require the naked eye. The inspection of instances is but preparatory to reflection upon principles. In the mining district the advantage of constant intercourse with the man who is doing things in mining, must be considered as exerting a greater influence in developing the understanding, than can be acquired in any of the technical schools, be they in New York, New Haven, Cambridge, or San Francisco.

I cannot do better in closing this address than to quote the following apt words from a lecture by Thomas Egleston, who established the Columbia School of Mines: "Sit at the foot of the practical man. When you know what he knows, with what you already know, you will know more than he knows."

THE tin-gravel industry of Northern Nigeria has been attracting attention. While some of the properties are doing exceedingly well, others are proving disappointing because the concentrate is found to contain excessive amounts of other minerals such as ilmenite. The Naraguta company is one of the successful mines. It was formed in January 1910, for the purpose of working in the province of Bauchi, and is a subsidiary of the Champion Gold Reefs of West Africa. C. G. Lush is consulting engineer and F. O'D. Bourke is manager. During the 14 months ending March 31, 551 tons of tin concentrate was won from 10 acres of land by sluicing and calabashing. The sale of this produce brought an income of £62,603, and after paying all expenses, including taxes, there was a profit of £27,161. Out of this, £17,500 has been distributed as dividend, being at the rate of 10%. The property bought by the company on flotation is 5 miles in extent, and other tracts are to be acquired. The results are excellent, considering the crude methods at present possible.

Rhodesian Gold Production

STAFF CORRESPONDENCE

The gold production of Rhodesia has been stationary for two years or more, and in many quarters the want of progress is interpreted pessimistically. It is no use denying that the country is in the hands of the big people, not so much, of course, as in earlier days, but still sufficiently to discourage the independent small man. Much of the pause in the increase of output has been caused by the big houses taking over the properties of small people, and suspending output while further development is done and machinery provided. In other cases properties have been recently developed by the big houses that promise to be important producers before long. The Cam & Motor and the Shamva are perhaps the most promising of these. In the meantime the Globe & Phoenix and the Eldorado continue to take the lead.

As regards the Eldorado, the reports reaching London indicate the presence of much rich ore. The mine was first developed about eight years ago and it was floated as a going concern by the Rhodesia Exploration & Development Co. in 1906. It is situated northwest of Salisbury. The ore is refractory and is treated in stamps, Chilean mills, grinding pans, and cyanide plant. H. Ewer Jones, the consulting engineer, reports that ore has now been exposed on the sixth and seventh levels for lengths of 1073 ft. and 875 ft., respectively, and that on the seventh level 100 ft. of the main lode averaged 4 oz. per ton over a width of 6 ft. On the eighth level, where the cross-cut from the shaft has met the lode, the orebody is 6 ft. wide and assays 5 oz. per ton. Also a winze has been sunk from the seventh level and the ore exposed for the whole of the 70 ft. sunk averages 43 dwt. over 5½ ft. The ore reserve is calculated at nearly 200,000 tons averaging 16.3 dwt. per ton. During the year ended March 31 last, 82,802 tons of ore was treated, yielding 48,264 oz., or 11⅔ dwt. per ton, a recovery of 94% of the estimated contents. The profit distributed to shareholders was £90,000.

THE WANDERER MINE, SELUKWE, RHODESIA.

One of the lowest grade gold-mining properties in Rhodesia is the Wanderer, Ashton, and Camperdown group in the Selukwe district. The ore is disseminated through the so-called banded ironstone. When the mines were first started the ore was of higher grade and operations were more profitable than nowadays, and from 1903 to 1906 the average annual output was 25,000 oz. Then came several lean years, and in 1909 the Camperdown was acquired. The annual amount of ore now treated is nearly 200,000 tons, of which rather more than one-half comes from the Camperdown and the remainder from the Ashton. During the past twelve months the assay value of the ore was 3 dwt., and 2.35 dwt. was recovered. The year before there was only 1¾ dwt. in the ore and 1.38 dwt. was recovered. It will be seen that the extraction is not high and is less now than a year ago. The ore is crushed in rolls and cyanided direct. Experiments are being made with a view to improving the metallurgical work. The profit for the past year was £15,000, and in all probability the current year will give such good results that the company will get on the dividend list again.

A Mexican Mill

Through the courtesy of C. H. [illegible] we present below a view of the Guerrero mill of the Compañía Minera Real del Monte y Pachuca, the well known Mexican property of the United States S. R. & M. Co. The mill, originally opened April 27, 1908, with 40 stamps, has been enlarged until the plant now includes 60 stamps of 1050-lb. weight crushing to 3 mesh. There are also 10 Evans-Waddell Chile mills, 12 Wilfley tables, 40 Johnston vanners, of which only 5 are in use at present, 12, 4 ft. 6 in. by 18 ft. tube-mills, of which 4 have El Oro lining, and a complete cyanide plant, of which the outside vats and agitators are shown in the illustration. The plant has a capacity of 15,000 tons and yields $[illegible],000 in silver bullion per month. The Real del Monte is possibly the oldest Spanish mine in Mexico. Work is known to have been in progress here as early as [illegible], and the patio process was applied here, for the first time, in 1557. It is a striking fact that a mine older than the invention of that process is still an important producer and has lived to be benefited by cyanide and electricity, after having used successfully the patio and the barrel process.

HACIENDA DE GUERRERO, HIDALGO, MEXICO.

An Engineer's Diary

An occasional engineer keeps a diary and the practice has so much to commend it that it deserves to become universal. I do not refer to the diary of personal interest, kept in fancy-covered gilt-edged books, begun January first, exactly, and discontinued February second, approximately, but to a systematic record of the progress of and incidents connected with the specific construction work in hand. Two questions relating to such a diary naturally suggest themselves to the engineer, namely, what class of information should be recorded, and would such a record have permanent value. Naturally the selection of the material will depend upon the office system of the engineer. The diary should be a supplementary record. For example, if a cost-keeping system has been adopted on the work and cost-keeping clerks are employed, the engineer's diary need not cover the feature of the work. If systematic cost-keeping is not otherwise arranged for, the diary should contain at least general cost records which the engineer readily can collect and compile daily.

During the progress of construction many troublesome situations arise of varied character. Often there are slight changes made in the plans as a result of situations and conditions which had not been anticipated. Difficulties arise in construction, and special methods are required to overcome them. Accidents occur to men and machinery and frequently both need mending and adjusting. In fact, the varied duties and responsibilities of the engineer in charge, in relation to matters of detail, are such that they constitute the most interesting part of his work. The methods used by him in overcoming the multitude of difficulties, large and small, incident to every piece of construction, go far toward determining the value of his services. Surely many of these methods, which at the time are regarded as mere incidents in the day's work, deserve permanent record.

That such a record, faithfully kept, would be of permanent value to the individual keeping it seems obvious. That it would be of value to others may not be so obvious and may be questioned by some. A diary which preserves the spirit and details of a piece of work will certainly always be of interest to the man who wrote it, and it will be of value to him in many ways. Before a job is finished it will become necessary to fix the date of some occurrence connected with it. If litigation arises the diary frequently comes in very handy when introduced as evidence and is given much weight in arriving at the truth and in establishing facts. The output per man per day on different classes of work under varying conditions is a matter of record with the diary keeper, and such data are of great value to the compiler and to others when similar conditions arise.

At the end of a job, or as soon thereafter as it becomes convenient, it becomes a very simple matter to edit the diary and thereby prepare an excellent article for publication in a technical paper, or for presentation before an engineering society. It is very important to note that an article so prepared would be rich in specific data and would be correspondingly valuable. While a job is in progress the resident engineer frequently is too busy to think of writing an article, and after the job is finished he often finds that he has forgotten many details which he feels should be included in a description of the work, so the article is never prepared. Many who are willing to contribute to technical literature never do so for that reason.

An article on construction, prepared after the work is completed, becomes largely a general description unless notes are available, which were taken during the progress of the work. General descriptions are of more interest than value to the reader, and are paid for proportionately. Specific information relating to engineering work is merchandise with a good market value, and diaries are specific information mines.—*Engineering & Contracting.*

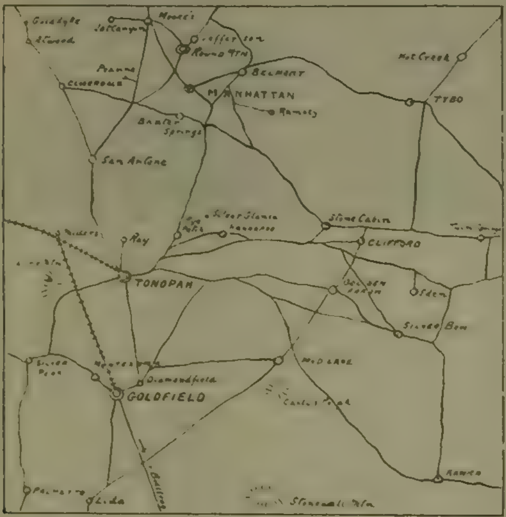
RESCUE TRAINING should not be undertaken just after eating, nor less than two hours since the last meal. During work in a mine the wearer should frequently rest by sitting down a few moments.

Developments at Manhattan

By An Occasional Correspondent

Manhattan, the 'Camp of the Pines' of central Nevada, launched in 1906 in the boom period of the Nevada excitement, now gives indications of making good. Its early promise is being realized in a substantial manner: one mining company has begun paying dividends, while lessees' operations have been profitable for some years. The froth and frenzy of the initial excitement, attended by the wave of insincere advertising of the unscrupulous, have passed, which is but a repetition of the history of every Western mining centre since the '50s, though the 'booming' was on an exaggerated scale in the case of Manhattan.

The status of mining is about as follows: No mines of importance, comparable with the Mizpah at Tonopah, the Combination at Goldfield, or the Nevada Hills at Fairview, were opened by the initial development. The ore found, while good, was scattered through the limestones and shales, and the owners were too busy scattering the shares to an eager public to pay much attention to serious mining. The position of Manhattan, 52 miles from the railroad at Tonopah, and 90 miles from that at Austin, and its situation at an elevation of 7000 ft., was against economical working. For the first mill the bill for freighting by railroad and team was said to have been $25,000. Small leasing operations predominated almost from the outset. By the fall of 1907, when the panic crippled practically all the banks of Nevada mining districts, the parent companies were not only deeply indebted to the banks, but their shares were scattered across the continent. Over 300 companies were affected.



PART OF NEVADA.

The spring of 1908 saw the first mill of importance in operation: this meant some ready money for the hungry lessees. The yield from the ore-dumps, however, went principally to satisfy the banks, yet it put things on a more substantial footing. The mill was erected on Mustang hill, and belonged to the Manhattan Ore Reduction & Refining Co.; it was subsequently purchased by the War Eagle company and is thus known. Organized and built upon the results of the experimental work of Francis L. Bosqui by J. H. G. Wolf, with the support of several mining companies, it has been the underlying means, by running as a custom plant, of holding men at the camp and furthering deep development. The treatment involves crushing by stamps, sliming all the pulp in tube-mills, precipitating with zinc-dust in a Merrill press. The mill was designed throughout for 20 stamps with tube-mills, or a capacity of 100 tons per day; 10 stamps only have been erected as yet. The advent of electric power in 1909 from the big plant that supplies all southwestern Nevada, by promoting cheaper mining and working of the ores, coupled with the discovery at the same period of placer gold on the bedrock of Manhattan cañon through a length of 5 miles, were the means of bringing the district back into public notice. The progress has been marked and substantial since then. For example, an orebody has been found and has yielded to date $250,000 in the Big Four mine on Gold hill. This property's surface was pecked at superficially in the early days, and, though favorably situated near the western end of the anticlinal dome or uplift in which valuable ores are found, no serious prospecting was attempted. This orebody is not exhausted, and is being explored at 400 ft. in depth; the ore is sulphide and yields about $40 per ton, with a reputed mill-extraction of 95%. The discovery of the Big Four orebody has encouraged more extensive development generally, particularly on Gold hill. The Litigation Hill end (east) has yielded considerable ore from shallow depths (so far) from the main lode traversing that section. Base ores, but of high value, have been developed from the Consolidated property eastward, but the ores of the remainder of the camp are practically free milling, requiring, at the most, all-sliming and cyaniding. The yield of the mill for the past twelve months, treating 11,500 tons, is reputed to have been $316,918, or some $28 per ton. This should be gratifying to the observers who visited the camp only in the early days, when so much chicanery and exploitation of the unwary were rampant. Manhattan may yet become an important producer, and while it will probably never yield as Tonopah and Goldfield have done, it may rank well with any of the late desert camps.

The yield of placer gold of the cañon is said to have been $300,000. The gold is coarse, angular, has quartz attached frequently, and gives but little evidence of having traveled far. How profitably the above yield has been won is not known; its chief significance is in the fact that while geologists have determined the surface erosion to have been relatively slight, placer gold is persistent for six miles or more into Big Smoky valley. As in the ancient channels of California, the valuable gravel, $5 to $15 per yard, is at or near bedrock.

Pangasinan, Philippine Islands

An examination of the northern portion of Pangasinan has been made by Mr. Fanning of the division of mines, Bureau of Science, in order to investigate the reported occurrence of oil, gold, copper, and other minerals. About 300 square miles of territory was covered and the essential features of the geology were determined and mapped. The detailed report and geological map is on file at the Bureau of Science and is open to the inspection of those interested. In brief, Tertiary sedimentaries of limestone, sandstone, and shale occur over the area except to the south and east. The structure is monoclinal with gentle dip to the northwest. Some slight folding has taken place, but there is no evidence of extensive faulting or shearing. Many persons have reported that oil seepages are frequently seen in the rainy season, and that the smell of gas is distinct. The examination was made in the dry season and no evidence of oil was seen, although the structure is adapted to oil accumulation. The area most favorable for such accumulation extends from Anda on the north to Balincaguin on the south and from west of Bani to Alaminos on the east. Artesian wells are soon to be bored at Anda, Bani, and Alaminos, which will probably give some evidence as to the possibility of oil. Some of the adjacent area can still be located as placer claims; or lease on occupied land can be had for small sums. The district was further examined for the occurrence of the valuable metals and the existence of gold, silver, copper, lead, zinc, and bismuth has been confirmed. However, as far as is now known, the deposits are of no commercial value.

Signaling From Mine Cages

A new device which permits those in the cage to signal and telephone to and from elevator cages when the latter are in motion, and which is of especial value for mine hoists, because the usual bells, whistles, etc., used are unreliable even for shafts of medium depth, has been put out by the Wernerwerke of the Siemens-Halske Co., Charlottenburg. The simplest signaling device uses two uncovered wires which hang free and may be pressed together at any point of their length, thus making electric contact and giving the signal. Where the speed is but moderate, the usual press-buttons may be employed, but where the cage travels rapidly and the service is regular, such devices do not suffice. The signaling arrangement proposed by Ryba has either two free-hanging wires with sliding contact, or employs the cage cable as one conductor; but as many separate signal devices are necessary as there are levels from which it is wished to signal; and where the mine is deep and the levels numerous, there is risk of tangling and breaking of free-hanging conductors. Another apparatus employs steam or compressed air which operates a whistle. A device patented in Germany about 1881 used the cable as return electric conductor; but as cables are liable to part at high speeds, and as the insulation was not perfect, it had no success.

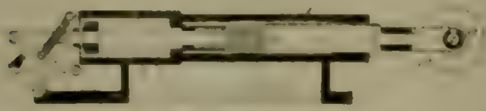


FIG. 1. SECTION THROUGH SIGNAL APPARATUS.

The sender of the device here illustrated is shown in lengthwise section in Fig. 1. In the cast-iron cylinder *a* the spiral spring *b* moves the piston *c* when the hand-lever *d* sets free the latch *e*. At the free end of the piston there is a loosely hinged contact roller *f*, which a hollow, hard-rubber cylinder *h* insulates from its shaft *g*. The conductors *i* (Fig. 2 and 3) of profile wire of 100 sq. mm. cross-section, and weighing 0.9 kg. per metre, or say 1.8 lb. per yard, are attached by wrought-iron clamps *k* to double-bell porcelain insulators *l*, which are protected from mechanical injury by hard rubber and are attached by clamping-plates *m*, *m*, to the shaft-framing *n*, every three metres (9.84 ft.). The current is furnished by eight elements of 11.3 volts and 4 amperes; the signal is given by a 'buzzer'. Fig. 4 shows the entire system.

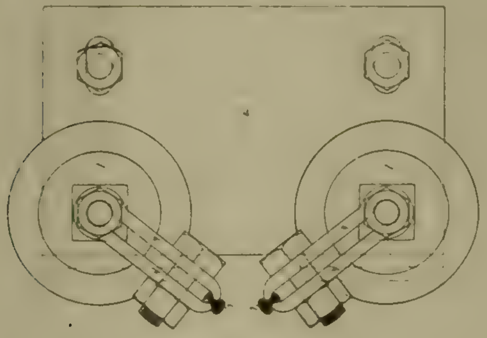

FIG. 2. PLAN.

Recent extended tests thereof have been made by the Prussian State Mining Inspection Department at Louisenthal. The place selected for the experiments is in the wettest portion of the mine, where the water constantly splashes from the levels into the shaft; the length of this section being 98 ft. The signal sender was built into the uppermost of the front section of the elevator cage, under the roof. In order to set the apparatus in function, it is only necessary to lift the lever *d* which frees the pawl *e*. The pressure of the spiral spring *b* then forces the contact roller *f* against the contact conductors *i*, thus closing the circuit and setting off the alarm. To repeat the signals the lever *d* is raised and lowered as often as is required; in fact, the Morse code may be used.

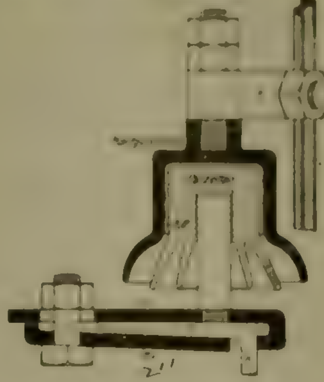

FIG. 3. CONDUCTORS.

Instead of the ordinary alarm, buzzer, bell, or other similar signal, there was also employed in the tests an electric horn. The signals were given at a cage speed of 1378 ft. per minute, 1186 ft. being the highest permitted for miners. The experiments, which were continued throughout an entire year, show that during this time the appparatus was thoroughly reliable. This is the main essential of such a device. The running of the conductors interfered with nothing else, and was itself attended with no special difficulty. Attempts have been made to telephone from the moving cage to the levels; there is, however, but little use for such facilities, especially when the cage is in rapid motion, as the stopping place would be

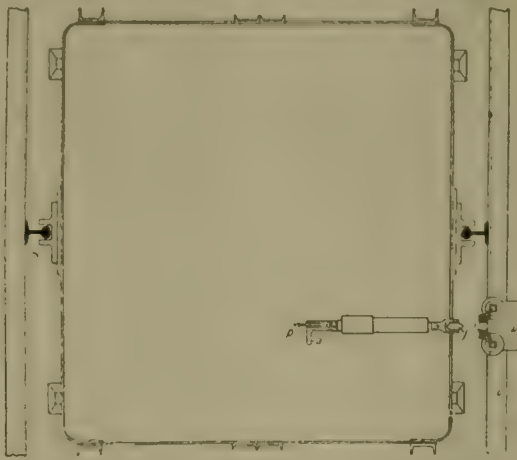

FIG. 4. GENERAL ARRANGEMENT OF SIGNAL APPARATUS.

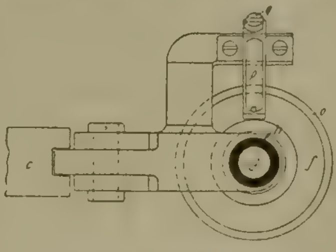

FIG. 5. SIDE VIEW.

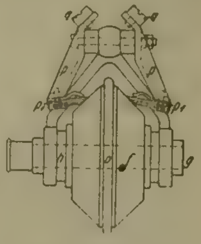

FIG. 6. END VIEW.

reached before telephonic connection were established. For cases of danger, however, the contact roller *f* could be altered as in Fig. 5 and 6; there being a hard-rubber disk between two parts fully insulated from each other. Above the roller there would be a spring current-taker *pp*, connected with the contact strip *i* and the cage telephone by the screws *q*. In telephoning, the operation would be the same as in signaling; but in rapid running the noise of the cage would vitiate all attempts. For telephoning from the cage when standing still, the arrangement shown in Fig. 5 and 6 would be unnecessary.

Loss of Treasure in Ships

By Alex. Del Mar

There are but few accounts of the loss of treasure in ships before the discovery of America, the most notable one being a sum of livres, probably equal in silver metal to about $200,000 of the present day, sent by Blanche, regent of France, to Louis IX, then at Acre in Syria, and lost at sea. But after the Spaniards began to plunder the New World, these losses became so numerous and important that they largely influenced the flow of the precious metals, the course of trade, and the finances and politics of Europe. The following list, covering the sixteenth and seventeenth centuries, though probably imperfect, is the result of considerable research:

1502. The fleet of Francisco de Bobadilla was lost off San Domingo, with 200,000 castellanos of gold, equal in fine metal to about $600,000 of the present day: "the product of two years of unexampled cruelty and oppression." (Prescott, 'Ferd. and Isabella', II, 500.)

1522. December 20. Eighty-eight pesos in gold bars and the wardrobe of Montezuma, rich with jewels, among them pearls the size of hazelnuts, shipped by Cortes to the king of Spain, captured by a French corsair named 'Jean Florin'. (Helps, 'Spanish Conquest', III, 16.)

1572. The Lisbon fleet from Brazil with half a million of gold crowns captured by the Dutch. (Motley, 'Dutch Republic', p. 476.)

1573. August 9. Drake returned from a piratical voyage on the Spanish Main with such a quantity of gold and silver that he was able to divide 4700% net on the stock of the 'adventurers' who had fitted him out. The booty was so vast that much of it had to be buried in Mexico and may never have been recovered. (Merchants 'Mappe of Commerce', 1683; Beckett, biography.)

1580. November 3. Drake returned from his cruise around the world with $4,000,000 in gold and silver captured from the Spaniards. In the 'Cacafuego' alone he found 13 chests of coined money, 80 pounds of gold, 6 tons of unrefined silver, besides wrought plate to a great amount. ('Halcyon Age', p. 3.)

1586. Drake plundered and sunk a number of Spanish galleons, some of them laden with treasure, but the amount lost is not known.

1587. Drake sunk 100 Spanish vessels, 10,000 tons, some of them laden with treasure, in Cadiz harbor.

1588. July 19. The Spanish Armada defeated by the English in the Channel. The survivors attempted to escape by sailing to the north of Scotland. Several were wrecked on the Scottish coast with a large amount of treasure. This is believed to still lie at the mouth of one of the Scotch rivers.

1598. The Spanish galleon 'Good Jesus', bound from the isthmus of Panama to Spain, was lost with $2,400,000 in gold and silver. (E. Howland, 'Ocean's Story'.)

After the English came the Dutch. The Spaniards had now removed the home port for their plate ships from Seville to Cadiz, which was much better defended.

1626. Admiral Peter Hein surprised the Spanish fleet off the northern coast of Brazil and captured several galleons with rich booty, much of which was lost in the engagement; amount not stated.

1628. September 8. Admiral Hein intercepted the Spanish plate ships off the coast of Cuba and pursued them into the bay of Matanzas, where he made himself master of the whole fleet with its rich lading, amounting in value to more than 11,600,000 florins. He himself fell in action in the following year.

1656. Notwithstanding the security of the port of Cadiz, the British admiral Blake had the temerity to attack it and sink the entire plate fleet which had just arrived from America, all but one vessel, on board of which he found upward of two million dollars. (Anderson, 'Hist. of Com.', II, 438.)

1657. Next year Admiral Blake attacked and sunk the entire Spanish plate ship at the isle of Tenerif, one of the Canaries. The treasure lost on this occasion was greater than that of the preceding year. The consequences to the Crown of Spain were most disastrous. *(Ibid.)*

After the Peace of Ryswick, 1697, these attacks upon the Spanish plate fleets ceased for a brief period, when new circumstances arose to revive them; so that the loss of treasure in ships during the eighteenth century was greater than it had ever been before.

California Oil Dividends

Dividends aggregating $694,038 were paid during July by California oil companies.

July Copper Review

By Misha E. Appelbaum

Although the copper market was firm throughout the month of July, very few transactions took place during the last two weeks of that month. The price fluctuated between 12⅝ and 12¾c., delivered 30 days, for electrolytic, and 12⅞ to 13c., delivered 30 days, for Lake. The deliveries for the month of July showed, as expected, large European consumption, and the falling off in domestic deliveries showed a natural shrinkage, which usually occurs in July and August of every year. The large decrease in the production cannot be interpreted as a favorable factor for the reason that while it helped to reduce the surplus, such low production cannot be anticipated in future, it having been due this month to climatic conditions. The surplus on the first of August, both here and abroad, was smaller than for quite some time past, and with a domestic revival of business, copper would certainly advance, or at least rule steady at present prices. Should a revival not occur, lower copper prices are bound to prevail, as Europe cannot be expected to take larger quantities of copper, or even keep up present ratio.

Variscite Near Lucin, Utah

By Leon J. Pepperberg

[*]A glance into the shop windows of any city is all that is necessary to convince one that there is a large demand at the present time for what is termed craftsman or barbaric jewelry. This type of ornament consists of various precious and semi-precious stones and gem matrices worked into large and small settings of gold, platinum, silver, or alloy material and built along the lines of quaint oriental or other designs. A discovery of variscite deposit, which from surface indications promises gems of good quality and a considerable amount of matrix material, is then both of scientific interest and economic importance, since its occurrence in this locality has not been described heretofore and since it is well adapted to the manufacture of the types of ornaments mentioned above.

The gem deposit here described is in Sec. 22, T. 8 N., R. 18 W., of the Salt Lake meridian and base line, about four miles north of Lucin, a small station on the main line of the Southern Pacific railroad, and about seven miles east of the Nevada-Utah line. The group of hills occurring here is composed largely of igneous rock, quartzite, and some cherty-chalcedonic limestone. They stand out prominently in comparison with the surrounding flat treeless desert.

The deposit occurs on a brow of one of these hills where the quartzite which contains the variscite has a thickness of from 150 to about 180 ft. and can be followed along the strike for about 600 ft. Four claims have been located along the outcrop of the gem-bearing quartzite which strikes north and has a dip of about 35° easterly. The development consists of one 22 ft. shaft and three open-cuts, in addition to which there are natural exposures of the deposit. In several places the quartzite stands from 6 to 15 ft. above the surface, and it is so thickly studded with different grades of variscite that it is easily distinguished by the bluish-green tint of this mineral.

Variscite is a hydrated aluminum phosphate. In the Lucin deposit the purer specimens are commonly nodular, oolitic, and brecciated in structure, while those showing the concentric and mottled structures may be considered variscite matrix. When found in nodular form the variscite is commonly coated with a thin crust of white and cream colored phosphate mixed with lime. Large pieces of pure variscite composed entirely of small prismatic crystals, usually six sided, but rarely distinct, are common. The crystals give the fracture surface of such specimens a granular effect. The real fracture of the gem quality variscite, as well as the prevailing fracture of the less pure but homogeneous specimens, is conchoidal. In color the mineral ranges from a brilliant deep emerald or apple-green through the blue greens to colorless. It is sometimes transparent, though usually translucent. The lustre of variscite is vitreous. The hardness of specimens collected is from 4 to 5 in the scale of which the diamond is 10.

According to Dana,[1] variscite has the following chemical composition: $AlPO_4 + 2H_2O$ or $Al_2O_3.P_2O_5.4H_2O$ = phosphorus pentoxide 44.9, alumina 32.3, water 22.8 = 100.

Since pure variscite is colorless, the greenish mineral as found in the deposit under discussion probably owes its color to some foreign substance.

A quantitative chemical analysis of the mineral has not been made, but careful tests showed the presence of minute amounts of iron, calcium, and a trace of chromium; consequently it is assumed that the salts of these impurities impart color to the variscite. No copper was detected. When the mineral is heated in the closed tube, much water, slightly alkaline, is driven off, while the mineral assumes a weak rose color; the [illegible] portion it becomes white. Before the blowpipe in the forceps it is infusible, but upon partial dehydration it turns a pale purple or rose-violet color, which disappears upon prolonged intense ignition, the mineral finally becoming white. If treated with cobalt solution and heated before the blowpipe it becomes blue. When treated with acid and held in the flame it imparts a greenish tinge to the flame, due to phosphoric acid. If the powdered mineral is mixed with soda and heated in the closed glass tube it develops ammonium carbonate. Variscite is insoluble in acids before heating, but afterward dissolves readily in acids and alkalies.

The quartzite in which the gem is found is of Carboniferous age, probably Pennsylvanian. It is a member of the Weber quartzite, locally calcareous, intercalated with minor Parallel Survey. The portion of this formation exposed at this locality consists of strata of massive white, gray, and reddish quartzite, localy calcareous, intercalated with minor blue-gray and white limestone beds. These beds have been highly metamorphosed, probably during a period of folding and faulting and the intrusion of Tertiary volcanic rocks. These consist of rhyolite and basalt. The forces which produced folding and faulting shattered and sheared the strata of quartzite in which the variscite is found into a sort of block breccia. After brecciation, solutions laden with silica and phosphoric acid, alternately entered the network of channels in the fractured quartzite and cemented the fragments together with chalcedony and variscite. Almost all of the angular cavities in the brecciated quartzite have been filled by these secondary deposits, but no replacement of the quartzite by these minerals was noted.

The alternate deposition of chalcedony, chert, variscite, brown limonite, wardite (?), and allied phosphates, has given certain specimens a banded structure showing concentric layers of these minerals, while other specimens are composed of but one kind of material and show no banding. The matrix presents many odd patterns and pleasing color combinations. These are due to the filling of small fractures in the variscite breccia by material of different chemical composition, or to the concentric layers of the various materials which enter into the make-up of the rock. Some of the mottled patterns are known to the trade as 'cobweb' or 'turtle back' matrix.

According to the U. S. Geological Survey,[2] three deposits producing gem variscite have been opened in Utah, one specimen has been sent in from Nevada, and crystallized variscite has been found in Montgomery county, Arkansas. From the above statement, and the fact that the newly discovered deposit of variscite with which this report is concerned is also situated in Utah, it is evident that the name 'utahlite' suggested for this gem by G. F. Kunz is particularly appropriate.

The conditions surrounding the variscite deposits of Utah are similar in every case so far reported; that is, the mineral is deposited as a cementing material in brecciated limestone, quartzites, or igneous rocks. It is usually associated with chalcedony and is much younger geologically than the rocks in which it is found. Several of the deposits are found in rocks of the same geologic age, but they seem to be strictly local deposits, and, from the evidence at hand, there is no apparent connection between them. Whether there is any relation between the variscite and the rock-phosphate deposits of Idaho, Utah, and Wyoming is not known. Some of the phosphoric acid of the variscite may have been derived from the rock-phosphate beds, which, in the case I have observed, are associated with younger geologic strata than the variscite. On this assumption the variscite would be younger geologically than the rock-phosphate beds. The phosphoric acid, however, may have been derived from the apatite in the igneous rocks of this region. Apatite is strongly attacked by waters containing carbonic acid, according to R. Muller.[3] Both lime and phosphoric acid pass into solution. Since pure cold water exerts a solvent action upon many silicates, it can readily be understood how corrosive must have been the hot acid and alkaline volcanic waters which existed in this region in Tertiary times. These waters undoubtedly played a large part in the transportation and deposition of the chalcedony, variscite, and other secondary minerals of the Lucin deposit. A part of the silica of the chalcedony may have been, and probably was, derived from the quartzite in which it is found.

---

[*] Published by permission of the Consulting Geologist of the Southern Pacific Company. A preliminary paper describing this deposit was read before the Le Conte Club, December, 1910.

[1] Dana, E. S. and J. D. 'A System of Mineralogy', 1906, p. 824.

[2] 'Mineral Resources of the United States', Pt. 2, 1908, pp. 853-57.

[3] *Nature*, Vol. 36, p. 460, 1887.

From surface indications the chief value of the Lucin deposit lies in the large amount of variscite matrix which it apparently contains. Very little gem quality variscite has been recovered, but it should be remembered that the property is as yet undeveloped. To the commercial world the gem is known as 'variscite,' 'utahlite,' 'amatrice,' 'chlorutahlite,' and 'variscite matrix.' It sells in the rough at from $5 to $15 per troy pound. Rare specimens command higher prices.

Rich Float

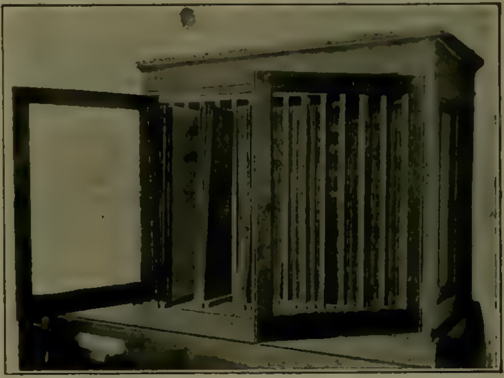
By Oscar H. Hershey

Many professional prospectors have 'rich float' stories as part of their assets. I propose to tell my 'rich float' story, as it shows what may be the outcome of a successful search for the source of gold-bearing float. Some years ago I was operating, in association with a gentleman from Missouri, a small gold-quartz mine in the valley of the South Fork of Salmon river, in Siskiyou county, California. Back of the mine there is a rugged mountain rising to about 3500 ft. above it. Occasionally I spent a day wandering over that mountain in search of quartz float; this float I subsequently ground in a mortar and washed in a gold-pan. About one piece out of three yielded from one to several very fine colors of gold, but for months I found nothing encouraging. I finally fell into the habit of not mortaring my float until the following morning, when I would be less disappointed by the result. One morning I had a particularly unpromising appearing lot, except one piece. That piece yielded so many colors of gold that it made me open my eyes wide in astonishment, and when I had time to realize that I, too, among prospectors, had struck 'rich float,' I had that peculiarly comfortable feeling that makes prospecting so fascinating. Now, at this stage, many prospectors fail to remember where they got the material, but I was not so fortunate. Calling my partner, I showed him what I had in the gold-pan; we quietly slipped into the brush and by a circuitous route reached the place. At first it seemed hopeless to find the source of the float, for it lay on a mass of loose débris that occupied a draw between two hard ledges of hornblende schist, and might have slidden a thousand feet down the mountain. I returned to the place several times. The first piece of float assayed at the rate of $350 gold per ton, but subsequently I found pieces that must have carried at least at the rate of $1000 per ton. It was a variety of gold quartz commonly found in the best veins of the region and contained galena, which mineral is present in many of the good mines of that part of the State. I had no reason to believe that it did not come from a pocket or mere seam. However, one day I crept under a thick clump of liveoaks and found the source of the float in an outcrop at the base of one of the hornblende schist ledges. Yes, it was high-grade ore, but when mined the entire orebody could be put in a hat. Much digging in the vicinity failed to develop anything else except thin seams yielding a few fine colors. Several of these seams had intersected and formed a pocket of gold quartz with all the physical characteristics (except as to extent) of the veins of that region. I had destroyed the asset quality of my 'rich float' story, and had lost a little of my respect for gold-bearing quartz float.

Returns supplied by the Witwatersrand Native Labour Association, Ltd., show the following results for the month of June: in gold mines, May, 190,392; June, 186,940; in coal mines, May, 8379; June, 8212; in diamond mines, May, 10,425; June, 10,597; total, May, 209,196; June, 205,749.

A Convenient Folio Case

The United States Geological Survey has been engaged for some years in the construction of a great topographic and geologic map of the United States. Individual topographic sheets are issued as completed, and as the geological surveys are likewise carried over each area a map with a brief text is printed. These reports are known as folios and are for sale at a nominal price, usually 25 cents each. The folios are 19 by 17 inches in size and exceedingly awkward to handle in the fields and to file for ready reference. At the same time, it is convenient to have the unfolded map. Where a large number are kept, the problem of storing them so that each shall be readily accessible is difficult. The accompanying illustration is from a photograph of one form of case which has been found quite satisfactory and which may be readily built in any cabinet shop. This case should be 1 ft. 9½ in. deep and 2 ft. 1 in. high, excluding top and base, or 2 ft. 8 in. including them. A convenient distance between partitions is 1¾ in., and a convenient width over all, 3 ft. The case may, however, be made wider if desired, so that it will stack readily with any of the standard unit bookcases. Such a folio case as illustrated will hold without crowding about 150 folios, each one being instantly accessible. An important point in the construction of the case is the sliding shelf on which the folios stand. Each shelf is made with a bit of tin or wood standing vertically at its rear end, to prevent folios being pushed in too far. The Survey is now publishing a field edition of the folios which are of ordinary book size, but the earlier ones are not available in this form. Indeed, many of the early ones are already out of print and difficult to obtain in any form. For library purposes the large form will probably continue to be preferred.



CASE FOR GEOLOGIC FOLIOS.

Copper Exports

The question has arisen as to where the large output of American copper has gone. Many believe that there is something unexplained in the decrease in the visible supply the last two years with America's record-breaking output. In this connection the following statistics, compiled by the *Boston News Bureau*, may be of interest. They show the total copper exports from the United States the last five years and the proportion taken by Germany, the Netherlands, and Great Britain:

Years.	U.S. Exports.	To Germany.	To Netherlands.	To Gt. Britain.
1910 ...	676,485,000	183,600,000	215,000,000	87,000,009

Petroleum Production in California

According to *The California Oil World* of Bakersfield, the State's total net petroleum production for the first six months of 1911 was 37,379,508 bbl. At the same rate the output for the year will be 77,171,542 bbl. The production last year was 74,849,700, making this year's estimated gain 2,321,842 bbl. This is the world's record for any State or country. The estimated field consumption for the six months was 2,461,797 bbl. The probable surplus for the year will be 7,065,000 bbl., which, added to the 39,000,000 in storage, will equal 46,000,000 bbl. The following is a statement of the net production for the first six months of 1911:

San Joaquin	Bbl
Coalinga	8,842,522
Kern River	6,221,124
Maricopa	1,885,686
Midway	9,142,513
McKittrick	2,660,838
Total	28,752,683
Southern:	
Salt Lake-Sherman	1,455,679
Los Angeles City	219,900
Whittier Coyote	544,019
Fullerton-Puente	2,806,008
Newhall	71,861
Ventura	210,005
Total	5,307,472
Coast Region:	
Santa Maria-Lompoc	3,286,659
Summerland	32,694
Watsonville	....
Arroyo Grande	....
Total	3,319,353
Grand total	37,379,508

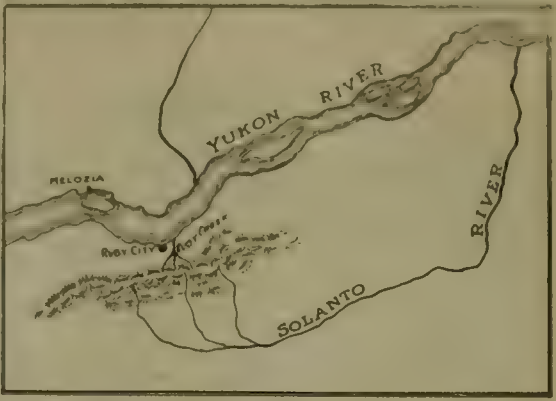
Kyshtim Corporation

The progress of the Kyshtim Corporation is of interest to Americans because so much of the capital and technical talent has been supplied from the United States. The company was formed in October 1908 to acquire the share capital of the Kyshtim Mining Works Co., which owns and operates iron mines, gold and copper deposits, and timber land in the Perm Government in the Southern Ural. R. Gilman Brown is consulting mining engineer, Walter G. Perkins is consulting metallurgical engineer, H. H. Knox is advisory consulting engineer, and Leslie Urquhart is general manager. Also, H. W. Turner, of San Francisco, is making a geological study of the copper deposits. During 1910, 89,509 tons of copper ore averaging 3.38% copper was mined, chiefly from the Koniukhoff mine. The production was 1674 tons of blister copper, containing 2578 oz. gold and 22,272 oz. silver. Subsequent information shows that from January 1 to June 10 of this year the production was 1712 tons copper. Until November, smelting was done at the old plant, and in that month the first new blast-furnace at Karabash started operations, followed by No. 2 in March of this year. Two basic-lined converters have also been erected. In addition, there is a small Siemens-Martin reverberatory at Kyshtim to treat the fine ore and flue-dust. It is now planned to build a new reverberatory at Karabash to extend the work in that direction. The whole of the copper is electrolytically refined on the spot. The copper ore reserve was calculated in June at 1,500,000 tons averaging 3½% copper. As regards the financial results for 1910 of the Russian company, the profit of the copper works was £64,335, of the ironworks £23,260, of the timber department £37,371, and in addition the sale of pyrite for sulphur content, income from gold gravel production and other small items brought the total receipts to £144,882. Against this, £85,047 was debited for general expenses, taxes, and interest on loans from banks, and £18,256 was paid as interest on mortgages. The amount paid to the credit of the Kyshtim Corporation was £41,579, which has been applied chiefly to debenture interest and management expenses.

Revival of an Alaskan Gold Camp

Staff Correspondence.

Ruby City is on the south bank of the Yukon, about 35 miles below Fort Gibbon, Alaska, where Ruby creek enters the river. Gold was found there some years ago, but no great amount was taken out. Ruby creek is short and heads in a low range of slate hills. Recently gold has been found along the creeks on the slopes opposite Ruby. These creeks flow into the Solatna river, which swings northeast and joins the Yukon thirty miles or thereabout above Ruby creek.



RUBY PLACERS AND QUARTZ FIELDS.

Good pay has been opened on Long creek, Big Dome, and on Fox gulch. Tom Aiken and Frank Manley have options already on some of the best properties.

The territory over which pay-dirt has been opened is about ten miles long, and the streak on Long creek is about a thousand feet in width.

Bob Martin, who has taken options along Fox gulch, has reached bedrock in two holes, and has a boiler on the way in.

Mining machinery is arriving daily at Ruby, but the trail to the creeks is so soft that none of it will be moved until winter. A sawmill has been set up.

During the first week in July gold-bearing quartz was found on Ruby creek itself, one mile south of the town. The vein was located by Henry Matson, M. B. Peterson, and Harry Weir. It is large and decomposed on the surface, but yields gold in the pan. As there has been no thought of quartz, there is no powder and no drill steel in Ruby. The vein has only been opened with picks and shovels when sufficiently weathered. The owners have uncovered quartz for 24 ft. and have got down 12 feet.

The richness of the rock as shown in their pannings has caused a quartz-staking stampede.

While there is much activity at Ruby, there is no demand for labor, as the work done is actual prospecting of their own ground by the locators. Only the men who want to take a chance for themselves, and who can go there with outfits or some money to carry them over the winter, should go into the district.

If the camp is proved it will be done this winter after thawing and hoisting plants are erected.

The creeks are long and the ground shallow; but it is all frozen and will have to be thawed. From the head of Long creek the whole country south to the mountains behind the Innoko, a hundred miles away, is a network of creeks and gulches, virgin ground of promise to the persistant and intelligent prospector.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Battery Foundations

The Editor:

Sir—From Mr. Waters' criticism of my foundation bolts in your issue of August 5, it would seem that I should have shown more views or have been more explicit in description. Perhaps some others have looked at my one view in the same light. The 5 in. angle is drilled for the bolt $2\frac{5}{8}$ at $2\frac{1}{2}$ in. from the edge, and the flange is then slotted from the hole to the edge. The bolt head thus bears, expressed by the boundary lines of its head, 5 in. on each of three sides and $2\frac{3}{8}$ in. on the fourth side, leaving no possible side strain upon the bolt.

M. P. Boss.

Lark, Utah, August 9.

The Economy of Dynamite

The Editor:

Sir—If the power generated in the explosion of 25 lb. of 40% gelatine dynamite such as is commonly used in the breaking of a 3 ft. round in a 4 by 7 ft. tunnel could be entirely utilized, it would be sufficient to break the rock to 6 in. cubes, hoist it to the surface from 1000 ft., and have enough surplus energy to operate a mill consuming 100 hp. continuously for four days. It would be sufficient to hoist the broken rock through a vertical distance of 250 miles. If it could be as advantageously applied as in the breaking of rock in a rock breaker it would be sufficient to break up the entire amount of rock from over 4000 ft. of a 4 by 7 ft. tunnel. These figures are derived by taking the initial pressure of dynamite at 120,000 lb. per square inch at the moment of explosion and assuming a consumption of 1 hp. for crushing one ton of rock in one hour. They are only approximations but are sufficiently correct for the purposes of this article.

From the above assumptions it may be calculated 1 lb. of dynamite will generate about 724,150,000 ft. lb. of energy and the cost of the power so generated would be about 32c. per horse-power month with powder at 16c. per pound. These figures bring out forcibly two important facts in connection with the use of dynamite: (1) that dynamite is an economical source of power; (2) that its use in connection with the breaking of rock is accompanied by an enormous waste of energy, beside which the generation and use of steam from coal or other forms of generating power is economy personified.
